In **Example 16.4**, we present the user with a text field and two command buttons. The user enters a number into the text field, then presses one of the two buttons. When the user clicks on the first button, we square the number; when the user clicks on the second button, we cube the number. We then display the result using a label component. To determine whether to square or cube the number, our event handler will need to identify which button was clicked by calling the *getSource* method of the *ActionEvent* class, as described in Table 16.6.

This example will demonstrate the following:

- how to handle an event originating from a button

- how to determine which component fired the event

Example 16.4 Simple Math Using *JButton*

```java
/* Simple Math Operations Using JButtons
   Anderson, Franceschi
 */

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class SimpleMath extends JFrame
{
 private Container contents;
 private JLabel operandLabel, resultLabel, result;
 private JTextField operand;
 private JButton square, cube;

 public SimpleMath( )
 {
  super( "Simple Math" );
  contents = getContentPane( );
  contents.setLayout( new FlowLayout( ) );

  operandLabel = new JLabel( "Enter a number" ); // text field label
  operand = new JTextField( 5 ); // text field is 5 characters wide

  // instantiate buttons
  square = new JButton( "Square" );
  cube = new JButton( "Cube" );

  resultLabel = new JLabel( "Result:" ); // label for result
  result = new JLabel( "???" );          // label to hold result

  // add components to the window
  contents.add( operandLabel );
  contents.add( operand );
  contents.add( square );
  contents.add( cube );
  contents.add( resultLabel );
  contents.add( result );

  // instantiate our event handler
  ButtonHandler bh = new ButtonHandler( );

  // add event handler as listener for both buttons
  square.addActionListener( bh );
  cube.addActionListener( bh );

  setSize( 175, 150 );
  setVisible( true );
 }

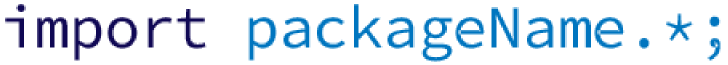
 // private inner class event handler
 private class ButtonHandler implements ActionListener
 {
  // implement actionPerformed method
  public void actionPerformed( ActionEvent ae )
  {
   try
   {
    double op = Double.parseDouble( operand.getText( ) );

    // identify which button was pressed
    if ( ae.getSource( ) == square )
      result.setText( Double.valueOf( op * op ).toString( ) );
    else if ( ae.getSource( ) == cube )
      result.setText( Double.valueOf( op * op * op ).toString( ) );
   }
   catch ( NumberFormatException e )
   {
    operandLabel.setText( "Enter a number" );
    operand.setText( "" );
    result.setText( "???" );
   }
  }
 }

 public static void main( String [ ] args )
 {
  SimpleMath sm = new SimpleMath( );
  sm.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

As you have seen in the previous examples, GUI applications use a number of Java classes. For Example 16.4, as well as the remaining examples in this chapter, we will use the bulk *import* statement, which replaces the individual class names with the wildcard character (*). Its syntax is:



```
import packageName.*;
```

Description

In this way, we write only one *import* statement per package (lines 5–7).

Notice that the *java.awt.event* package is different from the *java.awt* package. You might assume that importing *java.awt*.* also imports the classes in the *java.awt.event* package. That is not the case, however; we need to import both packages.

COMMON ERROR TRAP

The *java.awt.event* package is not imported with the *java.awt package*. Include import statements for both the *java.awt* and the *java.awt.event* packages.

At lines 51–74, we define our event handler, *ButtonHandler*, as a *private* inner class. Because clicking a button fires an *ActionEvent*, our event handler implements the *ActionListener* interface. Thus, we provide our code to handle the event in the *actionPerformed* method. Line 59 retrieves the data the user typed into the text field and attempts to convert the text to a *double*. Because the *parseDouble* method will throw a *NumberFormatException* if the user enters a value that cannot be converted to a *double*, we perform the conversion inside a *try* block.

The *if* statement at line 62 calls the *getSource* method using the *ActionEvent* object reference to test if the component that fired the event is the *square* button. If so, we set the text of the *result* label to the square of the number entered.

If the *square* button did not fire the event, we test if the source of the event was the *cube* button (line 64). If so, we set the text of the *result* label to the cube of the number entered. Actually, the test in line 64 is not necessary, because we registered our event handler as the listener for only two buttons.

So if the source isn't the *square* button, then the *cube* button must have fired the event. However, in order to improve readability and maintenance, it is good practice to check the source of the event specifically, in particular if additional buttons or components will be added to the application later.

SOFTWARE ENGINEERING TIP

Verify the source component before processing the event.

In the constructor, at lines 40–41, we declare and instantiate the *ButtonHandler* event handler, *bh*. At lines 43–45, we call the *addActionListener* method to register the handler on our two buttons.

The output of this example is shown in **Figure 16.7**. When you run this example, try entering a valid number into the text field, and press each button. Then try to enter text that cannot be converted to a number. Also, try deleting either statement that registers the event listener on the buttons (line 44 or 45), and run the application again.

16.7 Radio Buttons and Checkboxes

If you have ever completed a survey on the web, you are probably acquainted with radio buttons and checkboxes.

Radio buttons prompt the user to select one of several mutually exclusive options. Clicking on any radio button deselects any previously selected option. Thus, in a group of radio buttons, a user can select only one option at a time.

Checkboxes are often associated with the instruction “check all that apply”; that is, the user is asked to select 0, 1, or more options. A checkbox is a toggle button in that if the option is not currently selected, clicking on a checkbox selects the option, and if the option is currently selected, clicking on the checkbox deselects the option.

The *JRadioButton* and *JCheckBox* classes, which belong to the *javax.swing* package, encapsulate the concepts of radio buttons and checkboxes, respectively. We will present two similar examples in order to illustrate how to use these classes and how they differ. Both examples allow the user to select the background color for a label component. We display three color options: red, green, and blue. Using radio buttons, only one option can be selected at a time. Thus, by clicking on a radio button, the user will cause the background of the label to be displayed in one of three colors. Using checkboxes, the user can select any combination of the three color options, so the label color can be set to any of eight possible combinations. **Table 16.11** lists all these combinations.

Selecting Color Using Radio Buttons vs.Checkboxes

Using Radio Buttons
(1 selection possible at a time)

Color Selection			**Resulting Color**
red	**green**	**blue**	
●	○	○	red
○	●	○	green
○	○	●	blue

Using Checkboxes
(0 to 3 selections possible at a time)

Color Selections			**Resulting Color**
red	**green**	**blue**	
☐	☐	☐	black
☑	☐	☐	red
☐	☑	☐	green
☐	☐	☑	blue
☑	☑	☐	yellow
☑	☐	☑	purple
☐	☑	☑	blue-green
☑	☑	☑	white

Description

Table 16.12 shows several constructors of the *JRadioButton*, *ButtonGroup*, and *JCheckBox* classes.

Useful Constructors of the *JRadioButton*, *ButtonGroup*, and *JCheckBox* Classes

Constructors of the *JRadioButton*, *ButtonGroup*, and *JCheckBox* Classes

Constructors

Class	Constructor
`JRadioButton`	`JRadioButton( String buttonLabel )` constructs a radio button labeled *buttonLabel*. By default, the radio button is initially deselected.
`JRadioButton`	`JRadioButton( String buttonLabel, boolean selected )` constructs a radio button labeled *buttonLabel*. If *selected* is *true*, the button is initially selected; if *selected* is *false*, the button is deselected.
`ButtonGroup`	`ButtonGroup( )` constructs a checkbox labeled *checkBoxLabel*. By default, the checkbox is initially deselected.
`JCheckBox`	`JCheckBox( String checkBoxLabel, boolean selected )` constructs a checkbox labeled *checkBoxLabel*. If *selected* is *true*, the checkbox is initially selected; if *selected* is *false*, the checkbox is initially deselected.

Description

Selecting or deselecting radio buttons and checkboxes fires an *ItemEvent*. To receive this event, our event handler needs to implement the *ItemListener* interface, which has only one method, shown in **Table 16.13**.

***ItemListener* Method API**

`public void itemStateChanged( ItemEvent event )` An event handler that implements the *ItemListener* interface writes

code in this method to respond to the *ItemEvent* fired by any registered components.

Description

Note that selecting a radio button fires both an *ItemEvent* and an *ActionEvent*, so an alternative for radio buttons is to register a handler that implements the *ActionListener* interface. We have chosen to use an *ItemListener* for both radio buttons and checkboxes to demonstrate the similarities and differences between the two components.

Example 16.5 shows the color selection application using radio buttons.

Example 16.5 Selecting Colors Using *JRadioButtons*

```
/* Select a Color using JRadioButtons
   Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class ChangingColors extends JFrame
{
 private Container contents;
 private JRadioButton red, green, blue;
 private ButtonGroup colorGroup;
 private JLabel label;
 private Color selectedColor = Color.RED;

 public ChangingColors( )
 {
  super( "Selecting a color" );
  contents = getContentPane( );
  contents.setLayout( new FlowLayout( ) );

  red = new JRadioButton( "red", true );
  green = new JRadioButton( "green" );
  blue = new JRadioButton( "blue" );

  label = new JLabel( "Watch my background" );
  label.setForeground( Color.GRAY );
  label.setOpaque( true );
  label.setBackground( selectedColor );

  contents.add( red );
  contents.add( green );
  contents.add( blue );
  contents.add( label );

  // create button group
  colorGroup = new ButtonGroup( );
  colorGroup.add( red );
  colorGroup.add( green );
  colorGroup.add( blue );

  // create RadioButtonHandler event handler
  // and register it on the radio buttons
  RadioButtonHandler rbh = new RadioButtonHandler( );
  red.addItemListener( rbh );
  green.addItemListener( rbh );
  blue.addItemListener( rbh );

  setSize( 225, 200 );
  setVisible( true );
 }

 private class RadioButtonHandler implements ItemListener
 {
  public void itemStateChanged( ItemEvent ie )
  {
   if ( ie.getSource( ) == red )
      selectedColor = Color.RED;
   else if ( ie.getSource( ) == green )
      selectedColor = Color.GREEN;
   else if ( ie.getSource( ) == blue )
      selectedColor = Color.BLUE;

   label.setBackground( selectedColor );
  }
 }

 public static void main( String [ ] args )
 {
  ChangingColors cc = new ChangingColors( );
  cc.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

The various instance variables are declared at lines 11–15. The instance variable *selectedColor*, which is initialized to red, will store the choice of the user and will be used to set the background of the *JLabel* component *label*. The three radio buttons and *label* are instantiated at lines 23–27. At line 23, we use a *JRadioButton* constructor with two arguments to instantiate the radio button *red*. The first argument is the title of the radio button; the second argument, *true*, specifies that *red* is selected. Thus, when the window appears, the *red* radio button will be selected. In order to reflect the effect of the selected radio button, we set the background color of the label to red at line 30.

At lines 24 and 25, *green* and *blue* are instantiated using the *JRadioButton* constructor with only a *String* argument, specifying the radio button titles. The four components are added to the content pane at lines 32–35.

At lines 37–41, we instantiate a *ButtonGroup* object, then add the *red*, *green*, and *blue* radio buttons to *colorGroup* so that they will be mutually exclusive selections.

At lines 43–48, we instantiate our event handler, *RadioButtonHandler rbh*, and call the *addItemListener* method to register the listener *rbh* on the three radio buttons.

At lines 54–67, the *private* class *RadioButtonHandler implements* the *ItemListener* interface. The only method of *ItemListener*, *itemStateChanged*, is overriden at lines 56–66. Inside *itemStateChanged*, we use an *if/else* statement to determine which radio button was selected in order to set *selectedColor* to the appropriate color.

COMMON ERROR TRAP

Forgetting to make *JRadioButtons* part of the same *ButtonGroup* makes them independent and not mutually exclusive.

Figure 16.8 shows a run of the example after the user has clicked on the *green* radio button. Try running the example and clicking on each radio button. Try modifying the code; for example, delete the lines adding the radio buttons to the button group, then compile and run the program again.

Figure 16.8 Running Example 16.5

Description

Example 16.6 shows the color selection application using checkboxes.

Example 16.6 Using *JCheckBoxes*

```java
/*  Using JCheckBoxes
    Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class MixingColors extends JFrame
{
 private Container contents;
 private JCheckBox red, green, blue;
 private int redValue, greenValue, blueValue;
 private JLabel label;

 public MixingColors( )
 {
  super( "Selecting a color" );
  contents = getContentPane( );
  contents.setLayout( new FlowLayout( ) );

  red = new JCheckBox( "red" );
  green = new JCheckBox( "green" );
  blue = new JCheckBox( "blue" );

  label = new JLabel( "Watch my background" );
  label.setOpaque( true );
  label.setForeground( Color.GRAY );
  label.setBackground( new Color ( 0, 0, 0 ) );

  contents.add( red );
  contents.add( green );
  contents.add( blue );
  contents.add( label );

  // create CheckBoxHandler event handler
  // and register it on the checkboxes
  CheckBoxHandler cbh = new CheckBoxHandler( );
  red.addItemListener( cbh );
  green.addItemListener( cbh );
  blue.addItemListener( cbh );

  setSize( 225, 200 );
  setVisible( true );
 }

 private class CheckBoxHandler implements ItemListener
 {
  public void itemStateChanged( ItemEvent ie )
  {
   if ( ie.getSource( ) == red )
   {
    if ( ie.getStateChange( ) == ItemEvent.SELECTED )
      redValue = 255;
    else
      redValue = 0;
   }
   else if ( ie.getSource( ) == green )
   {
    if ( ie.getStateChange( ) == ItemEvent.SELECTED )
      greenValue = 255;
    else
      greenValue = 0;
   }
   else if ( ie.getSource( ) == blue )
   {
    if ( ie.getStateChange( ) == ItemEvent.SELECTED )
      blueValue = 255;
    else
      blueValue = 0;
   }

   label.setBackground(
        new Color( redValue, greenValue, blueValue ) );
  }
 }

 public static void main( String [ ] args )
 {
  MixingColors mc = new MixingColors( );
  mc.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

The various instance variables are declared at lines 11–14. The instance variables *redValue*, *greenValue*, and *blueValue* will store the red, green, and blue intensity values, depending on which checkboxes the user selects. These values will be used to set the background color of the *JLabel* component *label*.

The three checkboxes and *label* are instantiated at lines 22–26. We use a *JCheckBox* constructor with a *String* argument that specifies the checkbox titles. The four components are added to the content pane at lines 31–34.

At lines 36–41, we instantiate the *CheckBoxHandler* event handler and register the *cbh* listener on the three checkboxes by calling the *addItemListener* method for each checkbox.

At lines 47–76, we define the *private* inner class, *CheckBoxHandler*, which *implements* the *ItemListener* interface. The only method of *ItemListener*, *itemStateChanged*, is overriden at lines 49–75. Inside *itemStateChanged*, we first use an *if/else* statement to determine which checkbox fired the event. We then use a nested *if/else* statement to determine if that checkbox has just been selected. The *getStateChange* method in the *ItemEvent* class returns this information. Its API is shown in **Table 16.14**. The *ItemEvent* class provides the *static int* constants *SELECTED* and *DESELECTED* for convenience in coding this method call. Every click on our checkboxes will fire an event, so calling the *getStateChange* method helps us to distinguish between the event fired when the user selects a checkbox from the event fired when the user deselects a checkbox.

A Useful Method of the *ItemEvent* Class

Return Value	**Method Name and Argument List**
`int`	`getStateChange( )` returns the state of the checkbox. If the checkbox is selected, the value *SELECTED* is returned; if the checkbox is deselected, the value

	DESELECTED is returned, where *SELECTED* and *DESELECTED* are *static int* constants of the *ItemEvent* class.

Description

If the source checkbox was selected, we set the corresponding color value to 255 (lines 54, 61, and 68). If the source checkbox was deselected, we set the corresponding color value to 0 (lines 56, 63, and 70). For example, if the *red* checkbox is the source of the event, then we check whether the *red* checkbox was selected. If so, we set *redValue* to 255. Otherwise, the red checkbox must have been deselected, so we set *redValue* to 0.

At lines 73–74, we set the background color of *label* to a color we instantiate using the values of *redValue*, *greenValue*, and *blueValue* for the color's respective intensities of red, green, and blue.

Figure 16.9 shows a run of the example after the user has selected the red and green checkboxes.

16.8 Programming Activity 1: Working with Buttons

In this activity, you will work with two *JButtons* that control one electrical switch. Specifically, you will write the code to perform the following operations:

1. If the user clicks on the “OPEN” button, open the switch.
2. If the user clicks on the “CLOSE” button, close the switch.

The framework for this Programming Activity will animate your code so that you can check its accuracy. **Figure 16.10** and **Figure 16.11** show the application after the user has clicked on the button labeled “OPEN” and the button labeled “CLOSE”, respectively.

Figure 16.10 User Clicked on “OPEN”

Description

Figure 16.11 User Clicked on “CLOSE”

Description

Instructions

Copy the source files in the Programming Activity 1 folder for this chapter to a folder on your computer. Note that all files should be in the same folder.

Open the *JButtonPractice.java* source file. Searching for five asterisks (*****) in the source code will position you to the first code section and then to the second location where you will add your code. In task 1, you will fill in the code to instantiate a button handler and register the handler on the appropriate components. In task 2, you will code the *private* class implementing the listener interface that handles the event generated when the user clicks on either button. Be careful: The class name you use for the handler in the first task needs to be the same as the name you use in the second task. It could be helpful to complete task 2 first. **Example 16.7** shows the section of the *JButtonPractice* source code where you will add your code.

Example 16.7 Location of Student Code In *JButtonPractice.java*

```
        ...
        open = new JButton( "OPEN" );
        contents.add( open );
        close = new JButton( "CLOSE" );
        contents.add( close );

        // ***** 1. Student code starts here
        // declare and instantiate the button handler
        // and register it on the buttons
        // end of task 1

        setSize( 500, 375 );
        setVisible( true );
    }

    // ***** 2. Student code restarts here
    // Code a private class to implement the correct Listener
    // and its required method
    // To open the switch, call the open method with the statement
    //   open( );
    // To close the switch, call the close method with the statement
    //   close( );
    // The last statement of the method should be
    //   animate( );

    // end of task 2
```

Description

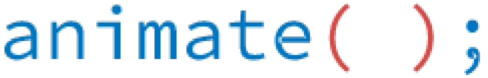
The framework will animate your code so that you can watch your code work. For this to happen, be sure that you call the *animate* method.

To test your code, compile and run the *JButtonPractice.java* file, then click on each button.

Troubleshooting

If your method implementation does not animate, check these tips:

- Verify that the last statement in your method inside the *private* class is:



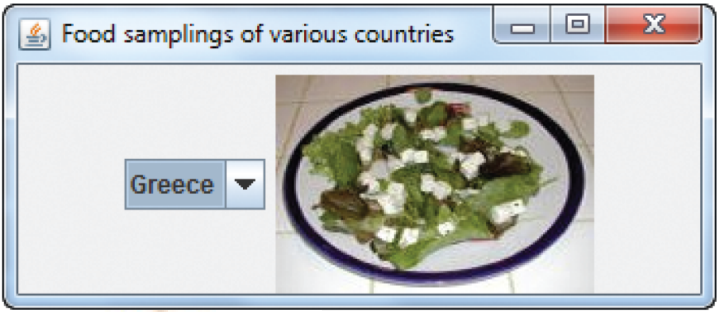
```
animate( );
```

- Verify that your listener is registered on the components.

- Verify that you have identified the origin of the event correctly.

DISCUSSION QUESTIONS

1. Explain why the *getSource* method is useful here.
2. Could you implement the preceding with *JRadioButtons* instead of *JButtons*? What interface would you implement? What method of the interface would you need to override? What type of event would you handle?



16.9 Combo Boxes

A *JComboBox* implements a drop-down list. When the combo box appears, one item is displayed, along with a button showing a down arrow. When the user presses on the button, the combo box “drops” open and displays a list of items, with a scroll bar for viewing more items. The user can select only one item from the list.

When the user selects an item, the list closes and the selected item is the one item displayed. A *JComboBox* fires an *ItemEvent*, so the event handler must implement the *ItemListener* interface, and thus, provide the *itemStateChanged* method.

Table 16.15 shows the APIs for a constructor and some useful methods of the *JComboBox* class. Note *JComboBox* is a generic class; thus, the constructor requires that you specify the class type of the items in the array that will make up the drop-down list. Often the class type is *String*. The *JComboBox* class provides the *getSelectedIndex* method, so that the event handler can determine which item the user has selected, and the *setSelectedIndex* method, which typically is used to initialize the default item displayed when the list appears. The *setMaximumRowCount* method allows us to specify how many items to display when the combo box opens. The user can use the scroll bar to move through all the items in the list.

Useful Constructors and Methods of the *JComboBox* Class

Constructors and Methods of the *JComboBox* Class

Constructor

Class	**Constructor**
`JComboBox`	`JComboBox( Object [ ] arrayName )`
constructs a new *JComboBox* component initially filled with the objects in *arrayName.* Often, the objects are *Strings*.	

Methods

Return value	**Method name and argument list**
`void`	`setSelectedIndex( int index )`
sets the item at *index* as selected. The index of the first item in the list is 0.	
`int`	`getSelectedIndex( )`
returns the index of the selected item. The index of the first item in the list is 0.	
`void`	`setMaximumRowCount( int size )`
sets the number of rows that will be visible at one time to *size*.	

Description

To illustrate how to use the *JComboBox* class, **Example 16.8** shows an application the user chooses from a list of countries and we then display a typical food from the selected country.

Example 16.8 Using *JComboBox* to Display Food Samplings

```java
/* Using JComboBox to show a sampling of international foods
 * Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class FoodSamplings extends JFrame
{
 private Container contents;
 private JComboBox<String> countries;
 private JLabel foodImage;

 private String [ ] countryList =
            { "France", "Greece", "Italy", "Japan", "USA" };
 private ImageIcon [ ] foods =
            {  new ImageIcon( "cheese.jpg" ),
               new ImageIcon( "fetaSalad.jpg" ),
               new ImageIcon( "pizza.jpg" ),
               new ImageIcon( "sushi.jpg" ),
               new ImageIcon( "hamburger.jpg" ) };

 public FoodSamplings( )
 {
  super( "Food samplings of various countries" );
  contents = getContentPane( );
  contents.setLayout( new FlowLayout( ) );

  // instantiate the components
  countries = new JComboBox<String>( countryList );
  countries.setMaximumRowCount( 4 );
  countries.setSelectedIndex( 2 );
  foodImage = new JLabel( foods[2] );

  // add components to the content pane
  contents.add( countries );
  contents.add( foodImage );

  // set up event handler
  ItemListenerHandler ilh = new ItemListenerHandler ( );
  countries.addItemListener( ilh );

  setSize( 350, 150 );
  setVisible( true );
 }

 private class ItemListenerHandler implements ItemListener
 {
  public void itemStateChanged( ItemEvent ie )
  {
   int index = countries.getSelectedIndex( );
   foodImage.setIcon( foods[index] );
  }
 }

 public static void main( String [ ] args )
 {
  FoodSamplings fs = new FoodSamplings( );
  fs.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

We declare and instantiate the instance variable, *foods*, as an array of *ImageIcons* (lines 17–22). The *foods* array stores images of the food samplings in the same order as the countries in our list. The instance variable *countryList*, an array of *Strings* declared and initialized at lines 15–16, holds the names of the countries to be displayed in the list.

At line 31, we instantiate *countries*, our *JComboBox*, by passing to the constructor the *countryList* array. To set the maximum number of items that the user will see when the combo box opens, we call the *setMaximumRowCount* method with an argument of 4 (line 32). At line 33, we programmatically select the third item, *Italy*, using the method *setSelectedIndex*. In order to match the displayed food sampling with the combo box selection, we initialize the *foodImage* label with the third element of the *foods* array (line 34).

Notice that our list of countries is arranged alphabetically to simplify finding a desired country. In this case, we have only five countries; however, with a longer list, the alphabetical ordering makes it easy for the user to find a particular item in the list. Another option is to display the most likely choice first, then display the remaining items in alphabetical order. For example, if most users reside in the United States, you could list “USA” first in the list, with the remaining countries alphabetized starting in the second position of the list.

SOFTWARE ENGINEERING TIP

Arrange list items in a logical order so that the user can find the desired item quickly.

At lines 48–55, we define the *ItemListenerHandler* event handler. To determine which item the user has selected, we call the *getSelectedIndex* method (line 52). Using that returned index, we call the *setIcon* method of the *JLabel* class to match the image of the label to the selected country.

Figure 16.12 shows the application after the user has clicked on *“Greece”* inside the combo box. Try running the example, then modify the number of visible rows by changing the argument of the *setMaximumRowCount* method, and run the example again.

16.10 Adapter Classes

We have learned that events are associated with event listener interfaces, and that we implement at least one interface in order to process an event. So far, we have used the *ActionListener* and *ItemListener* interfaces, each of which has only one method. For mouse events, there are two listeners: the *MouseListener* and the *MouseMotionListener*. The *MouseListener* interface specifies five methods to implement and the *MouseMotionListener* interface specifies two methods to implement.If we want to use *MouseListener* but need only one of its five methods to process a *MouseEvent*, we still have to implement the other four methods as “do-nothing” methods with empty method bodies. For convenience, Java provides **adapter classes**, each of which *implements* an interface and provides an empty body for each of the interface’s methods. For mouse events, the adapter classes are *MouseAdapter* and the *MouseMotionAdapter*. Thus, instead of implementing an interface, we can extend the appropriate adapter class and override only the method or methods we need. For example, if we want to process a *MouseEvent* using only one method of the five in the *MouseListener* interface, we can simply extend the *MouseAdapter* class and override that one method. We will do that in our next example.

SOFTWARE ENGINEERING TIP

When you need to implement only a few methods of a listener interface having more than one method, consider extending the corresponding adapter class instead.

16.11 Mouse Movements

A truly interactive application allows the user to point and click using the mouse. Any mouse activity (clicking, moving, or dragging) by the user generates a *MouseEvent*. When any mouse activity occurs, we will be interested in determining where on the window the user clicked, moved, or dragged the mouse. To determine the (*x, y*) coordinate of the mouse event, we can call two methods of the *MouseEvent* class, *getX* and *getY*, which are described in **Table 16.16**.

Useful Methods of the *MouseEvent* Class

Return Value	Method Name and Argument List

`int` `getX()`
returns the x value of the (*x,y*) coordinate of the mouse activity
`int` `getY()`
returns the y value of the (*x, y*) coordinate of the mouse activity

---

Description

Depending on the type of mouse activity, our application will implement either a *MouseListener* interface or a *MouseMotionListener* interface. As mentioned, both of the listener interfaces have been implemented as adapter classes that we can extend. The *MouseListener* interface includes the five *abstract* methods described in **Table 16.17**.

Methods of the *MouseListener* Interface

MouseListener Interface Method APIs

`public void mousePressed( MouseEvent e )`
called when the mouse button is pressed
`public void mouseReleased( MouseEvent e )`
called when the mouse button is released after being pressed
`public void mouseClicked( MouseEvent e )`
called when the mouse button is pressed and released
`public void mouseEntered( MouseEvent e )`
called when the mouse enters the registered component
`public void mouseExited( MouseEvent e )`
called when the mouse exits the registered component

Description

To illustrate how to use the *MouseAdapter* class, we will build a simple submarine hunt game. A submarine is hidden somewhere in the window, and the user will try to sink the submarine by clicking the mouse at various locations in the window, simulating the dropping of a depth charge. Each time the user clicks the mouse, we will indicate how close that click is to the submarine. If the user clicks too far from the submarine, we will display “In the water” in the title bar and draw a blue circle where the mouse was clicked. If the user clicks close to the submarine, we will display “Close …” in the title bar. Finally, if the submarine is hit, we will change the title bar to “Sunk!”, display the submarine, and remove the listener so that the game ends.

In this application, we want to design our classes so that they are as reusable as possible. To this end, we will design our classes using the **Model- View-Controller** architecture.

The **Model** encapsulates the application's functionality: It should be designed so that it can be reused in a different context, in particular with a different user interface.

The **View** encapsulates the user interface of the application: It should also be designed so that it can be reused with a different Model.

The **Controller** is the middleman between the View and the Model. When the user interacts with the View, the Controller asks the Model to perform some calculations, and then updates the View accordingly. If possible, the Controller should also be designed so that it is independent from the Model and the View so that it can be reused with other Views and other Models.

As much as possible, it is good design practice to separate the Model, the View, and the Controller. It makes the application components easier to design, code, maintain, modify, and reuse.

Figure 16.13 shows the UML diagram for this application. We first code our Model, the *SubHunt* class (**Example 16.9**). It encapsulates the submarine hunt game and enables us to create a game of a given size, enable play, and enforce the rules of the game.

Figure 16.13 UML Diagram for *SubHunt* and *SubHuntViewController*

Description

Example 16.9 The *SubHunt* Class

```
/* SubHunt class
*  Anderson, Franceschi
*/

import java.awt.Graphics;
import java.awt.Color;
import java.util.Random;

public class SubHunt
{
 public static int DEFAULT_GAME_SIZE = 300;
 public static int SIDE = 36; // size of submarine

 private int gameSize;
 private int xCtr; // x coordinate of center of submarine
 private int yCtr; // y coordinate of center of submarine
 private String status = "";
 private boolean hit;

 /** Constructor
 * @param newGameSize game size
 */
 public SubHunt( int newGameSize )
 {
  if ( newGameSize > SIDE )
    gameSize = newGameSize;
  else
    gameSize = DEFAULT_GAME_SIZE;
  // generate submarine center
  Random random = new Random( );
  xCtr = SIDE / 2 + random.nextInt( gameSize - SIDE );
  yCtr = SIDE / 2 + random.nextInt( gameSize - SIDE );
  hit = false;
 }

 /** getStatus
 * @return status
 */
 public String getStatus( )
 {
  return status;
 }

 /** getGameSize
 * @return gameSize
 */
 public int getGameSize( )
 {
  return gameSize;
 }

 /** isHit
 * @return hit
 */
 public boolean isHit( )
 {
  return hit;
 }

 /** play
 * @param x the x coordinate of the play
 * @param y the y coordinate of the play
 */
 public void play( int x, int y )
 {
  // is click within the submarine?
  if ( Math.abs( x - xCtr ) < SIDE / 2
       && Math.abs( y - yCtr ) < SIDE / 2 )
  {
    status = "Sunk!";
    hit = true;
  }
  // is click close?
  else if ( Math.abs( x - xCtr ) < 2 * SIDE
            && Math.abs( y - yCtr ) < 2 * SIDE )
    status = "Close ...";
  // click is too far from submarine
  else
    status = "In the water";
 }

 /** draw
 * @param g a Graphics object
 * @param x the x coordinate of the play
 * @param y the y coordinate of the play
 */
 public void draw( Graphics g, int x, int y )
 {
  if ( status.equals( "Sunk!" ) )
  {
    // draw sunken submarine
    g.setColor( Color.BLACK );
    g.fillRoundRect( xCtr - SIDE/2, yCtr - SIDE/2,
                     SIDE/2, SIDE, SIDE/2, SIDE/2 );

    g.fillRoundRect( xCtr - SIDE/4, yCtr - SIDE/3,
                     SIDE/2, SIDE/2, SIDE/4, SIDE/4 );

    g.drawLine( xCtr + SIDE/4, yCtr - SIDE/9,
                xCtr + SIDE/2, yCtr - SIDE/9 );

    // draw red depth charge
    g.setColor( Color.RED );
    g.fillOval( x - SIDE/4, y - SIDE/4, SIDE/2, SIDE/2 );
  }
  else if ( status.equals( "In the water" ) ) // draw blue circle
  {
    g.setColor( Color.BLUE );
    g.fillOval( x - SIDE/2, y - SIDE/2, SIDE, SIDE );
  }
  // else Close .    .    . , do not draw
 }
}
```

Description

Example 16.10 shows the *SubHuntViewController* class. It combines the View and the Controller. Later in the chapter, we will show you how to separate the View and the Controller in order to make the View reusable.

Example 16.10 The *SubHuntViewController* Class

```java
/* SubHuntViewController class
*  Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class SubHuntViewController extends JFrame
{
 private int x; // current x mouse position
 private int y; // current y mouse position
 private SubHunt sub; // submarine
 private boolean gameStarted = false;
 private Insets insets;
 private MouseHandler mh; // mouse event handler

 public SubHuntViewController( SubHunt newSub )
 {
  super( "Play!" );

  sub = newSub;
  // instantiate event handler and register listener on window
  mh = new MouseHandler( );
  addMouseListener( mh );

  // size window to include insets
  setVisible( true );
  insets = getInsets( );
  setSize( sub.getGameSize( ) + insets.left + insets.right,
           sub.getGameSize( ) + insets.top + insets.bottom );
 }

 private class MouseHandler extends MouseAdapter
 {
  public void mouseClicked( MouseEvent me )
  {
   x = me.getX( ) - insets.left;
   y = me.getY( ) - insets.top;
   sub.play( x, y );
   setTitle( sub.getStatus( ) );
   repaint( );
  }
 }

 public void paint( Graphics g )
 {
  if ( !gameStarted )
  {
   super.paint( g );
   gameStarted = true;
  }
  g.translate( insets.left, insets.top );
  sub.draw( g, x, y );
  if ( sub.isHit( ) )
    removeMouseListener( mh );
 }
}
```

Description

The constructor (lines 18–32) defines and displays the original View. The *MouseHandler* private class (lines 34–44) and the *paint* method (lines 46–57) make up the Controller. The Model is represented by the instance variable *sub* (line 13). When the user interacts with the View by clicking on the window, the Controller captures that information, calls the appropriate method of the *SubHunt* class, and updates the View accordingly.

In this game, the only mouse action we care about is a click; therefore, we are interested in only one method of the *MouseListener* interface: *mouseClicked*. To simplify our code, our handler extends the *MouseAdapter* class, which provides do-nothing implementations for the five *MouseListener* methods, so our event handler needs to override only the *mouseClicked* method.

At lines 11–16, we declare our instance variables. The *ints x* and *y* represent the *x* and *y* coordinates where the player clicked the mouse relative to the entire window. The *SubHunt* instance variable *sub* represents the submarine hunt game that we display inside the window. The constructor receives a *SubHunt* object as a parameter, which it stores in the *sub* instance variable on line 22. When the user plays, we use the *sub* reference to call the various methods of the *SubHunt* class to enable play and enforce the rules of the game.

In this example, we have set up the listener reference, *mh*, as an instance variable (line 16) rather than the reference as a local variable to the constructor, as we have done in previous examples. We define *mh* as an instance variable because, when the game is over, the event handler needs to access that listener to turn it off. The event handler is instantiated at line 24.

We want the listener to handle mouse clicks anywhere in the window, so we register the *mouseListener* on our window (*JFrame*) component, which is the *SubHuntViewController* object. Thus, we do not use an object reference to call the *addMouseListener* method, and line 25 is equivalent to:

```
this.addMouseListener( mh );
```

Description

When the user clicks inside a *JFrame window*, the *x* and *y* coordinates returned by the *mouseClicked* method are relative to the top-left corner of the window; that is, (0,0) is the top-left corner of the window. However, for a *JFrame*, the title bar is in the top-left corner. In fact, a *JFrame* has borders at the top (where the title bar is displayed), the left, the right, and the bottom. These four areas together are called the **insets** of the frame. Thus, in coding the sub hunt game, we need to adjust the *x* and *y* coordinates so that the game is played inside a rectangle that excludes the insets.

Figure 16.14 shows the *JFrame* and sub hunt game rectangles in gray and orange, respectively.

Figure 16.14 The Game Rectangle within the *JFrame*

Description

The *Insets* class (in the *java.awt* package) allows us to determine the sizes of the borders. The *getInsets* method of the *Container* class, inherited by *JFrame* and shown in **Table 16.18**, returns the *Insets* object for the current frame. The *Insets* class includes four *public* instance variables shown in **Table 16.19**, which we can access directly in order to retrieve the sizes of the four borders of the frame.

The *getInsets* Method Inherited from the *Container* Class

Method	Description
`Insets getInsets( )`	Returns an object representing the insets of this *Container*

Description

The Instance Variables of the *Insets* Class

Instance Variables	Description
`public int top`	The size of the top border
`public int left`	The size of the left border
`public int bottom`	The size of the bottom border
`public int right`	The size of the right border

Description

At lines 28–30, we retrieve the insets for the current *JFrame* and size the window so that its inside rectangle matches the dimensions of the rectangle of the *SubHunt* instance variable *sub*.

At lines 34–44, we define our mouse event handler, *MouseHandler*, as extending *MouseAdapter*. Inside the method *mouseClicked*, overridden at lines 36–43, we call the *MouseEvent* methods *getX* and *getY* to get the (*x, y*) coordinate where the mouse was clicked relative to the entire window. We adjust these values by the sizes of the insets before storing them in the *x* and *y* instance variables. Then we call the *play* method of *SubHunt* with *sub* (line 40) to process the play, passing the position of the click. Next, we update the title of the window by getting the updated status, and display that status in the window title bar by calling the *setTitle* method (line 41). Finally, we call the *repaint* method (line 42) to update the display. The *repaint* method is inherited from the *Component* class and has the API shown in **Table 16.20**. Since we cannot call *paint* directly, we call *repaint to* force a call to the *paint* method in order to update the drawing in the window.

The *repaint* Method API in the *Component* Class

Return Value	Method Name and Argument List
`void`	`repaint( )`
automatically forces a call to the *paint* method	

Description

For this game, we want to preserve any previously drawn shapes. Thus, in the *paint* method (lines 46–57), rather than clear the window and redraw every time, we set our flag *gameStarted* to *false* when the *game* starts (line 14). This causes us to call *super.paint* to clear the window the first time *paint* is called (lines 48–52) and then set *gameStarted* to *true* so that we skip any further calls to *super.paint*.

In order to draw the result of the last click, we first call the *translate* method of the *Graphics* class (line 53), passing the left and top insets to adjust the click position of the coordinate to the top-left corner of the sub hunt rectangle. The *translate* method's API is shown in **Table 16.21**. We then call the *SubHunt draw* method, passing the *Graphics* object *g* and the mouse position.

The *translate* Method of the *Graphics* Class

Method	Description
`void translate( int x, int y )`	translates the origin of the graphics context to the point (*x, y*) in the current coordinate system

Description

Finally, if the game is over, we remove *mh* as a listener to this object (line 56) by calling the *removeMouseListener* method, inherited from the *Component* class.

The *PlaySubHunt* class, shown in **Example 16.11**, includes the *main* method to create a *SubHunt* object and a *SubHuntViewController* application. **Figure 16.15** shows a run of this game. At this point, the user has sunk the submarine.

Example 16.11 The *PlaySubHunt* Class

```
/* PlaySubHunt class
*  Anderson, Franceschi
*/

import javax.swing.JFrame;

public class PlaySubHunt
{
 public static void main( String [ ] args )
 {
  SubHunt sub = new SubHunt( SubHunt.DEFAULT_GAME_SIZE );
  SubHuntViewController subGui = new SubHuntViewController( sub );
  subGui.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

Figure 16.15 A Run of the Sub Hunt Game

Description

The second interface related to mouse events is *MouseMotionListener*, which has two methods, *mouseMoved* and *mouseDragged*, shown in **Table 16.22**. Dragging the mouse is defined as the user moving the mouse with the mouse button pressed, but not released.

MouseMotionListener Interface Method APIs

MouseMotionListener **Interface Method APIs**

`public void mouseMoved( MouseEvent e )`

called when the mouse is moved onto a component

`public void mouseDragged( MouseEvent e )`

called when the mouse button is pressed on a component and the mouse is dragged

---

Description

In order to illustrate how to use the *MouseMotionListener* interface with a *MouseEvent* class, we will build a simple treasure hunt game that is similar to the submarine hunt game. A treasure is hidden somewhere in the window, and the user will try to find it, not by clicking the mouse button, but by moving the mouse inside the window. Depending on how close the mouse is to the treasure, we will display a message at the mouse location so that the user can find the treasure and win the game.

Figure 16.16 shows the UML diagram for the Treasure Hunt Game.

Figure 16.16 UML Diagram for the Treasure Hunt Game

Description

Again, we first code the Model, the class to encapsulate the functionality of our treasure hunt game (**Example 16.12**). It enables us to create a game of a given size, handle plays, determine when the game is over, and display the status of the game.

Example 16.12 The *TreasureHunt* Class

```java
/* TreasureHunt class
*  Anderson, Franceschi
*/

import java.awt.*;
import java.util.Random;

public class TreasureHunt
{
 public static int DEFAULT_GAME_SIZE = 300; // side of window
 public static int SIDE = 40; // side of treasure

 private int gameSize;
 private int xCtr; // x coordinate of center of treasure
 private int yCtr; // y coordinate of center of treasure
 private String status = ""; // message
 private boolean gameOver = false;

 /** Constructor
 */
 public TreasureHunt( int newGameSize )
 {
  if ( newGameSize > SIDE )
    gameSize = newGameSize;
  else
    gameSize = DEFAULT_GAME_SIZE;
  // generate treasure center
  Random random = new Random( );
  xCtr = SIDE / 2 + random.nextInt( gameSize - SIDE );
  yCtr = SIDE / 2 + random.nextInt( gameSize - SIDE );
 }

 /** getGameSize
 * @return gameSize
 */
 public int getGameSize( )
 {
  return gameSize;
 }

 /** isGameOver
 * @return gameOver
 */
 public boolean isGameOver( )
 {
  return gameOver;
 }

 /** play
 * @param x the x coordinate of the play
 * @param y the y coordinate of the play
 */
 public void play( int x, int y )
 {
  // is mouse within treasure?
  if ( Math.abs( x - xCtr ) < SIDE / 2
       && Math.abs( y - yCtr ) < SIDE / 2 )
  {
    gameOver = true;
    status = "Found";
  }
  // is mouse within half-length of the treasure?
  else if ( Math.abs( x - xCtr ) < ( 1.5 * SIDE )
            && Math.abs( y - yCtr ) < ( 1.5 * SIDE ) )
    status = "Hot";
  // is mouse within 1 length of the treasure?
  else if ( Math.abs( x - xCtr ) < ( 2 * SIDE )
            && Math.abs( y - yCtr ) < ( 2 * SIDE ) )
    status = "Warm";
  // is mouse within 2 lengths of the treasure?
  else if ( Math.abs( x - xCtr ) < ( 3 * SIDE )
            && Math.abs( y - yCtr ) < ( 3 * SIDE ) )
    status = "Lukewarm";
  else // mouse is not near treasure
    status = "Cold";
 }

 /** draw
 * @param g a Graphics object
 * @param x the x coordinate of the play
 * @param y the y coordinate of the play
 */
 public void draw( Graphics g, int x, int y )
 {
  g.setColor( Color.BLUE );

  if ( status.equals( "Found" ) ) // if found, draw treasure
  {
   g.setColor( Color.RED );
   g.fillRect( xCtr - SIDE / 2, yCtr - SIDE / 2, SIDE, SIDE );
   g.setColor( Color.GREEN );
   g.drawString( "$$$", xCtr - SIDE / 4, yCtr );
  }
  else
   g.drawString( status, x, y ); // display current status
 }
}
```

Description

The *status* (line 16) instance variable, a *String*, stores the state of the player's position compared to the location of the treasure. We also define a *boolean* flag variable, *gameOver*, which is initially *false* (line 17); when the user finds the treasure, we will change it to *true.*

In the constructor, we randomly generate the (*x*, *y*) coordinate for the center of the treasure and store the generated values in the *xCtr* and *yCtr* instance variables (lines 27–30).

The *play* method (lines 49–76) sets the value of *status*. If the player is far from the treasure, we set the value of *status* to "Cold." As the user moves closer and closer to the treasure, the value becomes "Lukewarm," then "Warm," and then "Hot," and finally "Found" when the player finds the treasure. If the treasure is found, we set the value of *gameOver* to *true* (line 59).

Like the sub hunt game, the *draw* method (lines 78–96) draws what is happening in the game. We first test if the value of *status* is "Found" (line 87). If it is, the treasure has been found and we reveal its location by drawing it (lines 89–92). If the treasure has not been found, we display the *String status* at the current mouse location (line 95), determined by the parameters *x* and *y* sent to the *draw* method.

Example 16.13 shows the *TreasureHuntViewController* class. Like the sub hunt example, it combines the View and the Controller. The constructor (lines 17–32) defines and displays the original View. The *mouseMoved*, *mouseDragged*, and *paint* methods (lines 34–43, 45–46, and 48–53, respectively) make up the Controller. The Model is represented by the instance variable *hunt* (line 14), where we store the *TreasureHunt* object sent to the constructor as a parameter (line 17).

Example 16.13 The *TreasureHuntViewController* Class

```
/* TreasureHuntViewController class
*  Anderson, Franceschi
*/

import javax.swing.JFrame;
import java.awt.*;
import java.awt.event.*;

public class TreasureHuntViewController extends JFrame
             implements MouseMotionListener
{
  private int x;
  private int y;
  private TreasureHunt hunt;
  private Insets insets;

  public TreasureHuntViewController( TreasureHunt newHunt )
  {
   super( "Play!" );

   hunt = newHunt;
   // application registers on itself
   // since it is a MouseMotionListener itself
   addMouseMotionListener( this );
   setSize( hunt.getGameSize( ), hunt.getGameSize( ) );
   setVisible( true );

   // resize window to include insets
   insets = getInsets( );
   setSize( getWidth( ) + insets.left + insets.right,
            getHeight( ) + insets.top + insets.bottom );
  }

  public void mouseMoved( MouseEvent me )
  {
   // get location of mouse
   x = me.getX( ) - insets.left;
   y = me.getY( ) - insets.top;
   hunt.play( x, y );
   repaint( );
   if ( hunt.isGameOver( ) )
     removeMouseMotionListener( this );
  }

  public void mouseDragged( MouseEvent me )
  { } // we do not want to process mouse drag events

  public void paint( Graphics g )
  {
   super.paint( g );
   g.translate( insets.left, insets.top );
   hunt.draw( g, x , y );
  }
}
```

Description

In this application, instead of coding the event handler as a *private* inner class, we define our application class as implementing the *MouseMotionListener* interface. As a result, our application is a listener, and we register the listener on itself. Thus, in our class definition, we include the clause *implements MouseMotionListener* (lines 9–10). Again, the instance variables *x* and *y* (lines 12–13) will store the current location of the mouse.

At lines 22–24, we register this *TreasureHuntViewController* object on itself as a *MouseMotionListener*. In this game, the only event we want to handle is the user moving the mouse. Because *TreasureHuntViewController* implements the *MouseMotionListener* interface, however, we must implement both the *mouseMoved* and the *mouseDragged* methods. Thus, we provide a method body for the *mouseMoved* method, and we implement *mouseDragged* with an empty body (lines 45–46). Note that we could not use the *MouseMotionAdapter* class because our application (which is the listener) already extends the *JFrame* class. Remember that a class can extend only one class, but can implement multiple interfaces.

The *mouseMoved* method is implemented at lines 34–43. At lines 36–38, we assign the (*x*, *y*) coordinate of the mouse position within the playing rectangle to the instance variables *x* and *y*, using the *getX* and *getY* methods of the *MouseEvent* class and by the sizes of the *left* and *top* insets. Then we call the *play* method of *TreasureHunt* with *hunt* (line 39) to process the play and call the *repaint* method (line 40) to update the window. If the game is over (i.e., the treasure has been found), we remove this object, the current *JFrame*, as a listener (line 42) by calling the *removeMouseMotionListener* method.

We begin the *paint* method (lines 48–53) with a call to the *paint* method of the *JFrame* superclass to clear the contents of the window. At line 51, we call the *translate* method with the *Graphics* object *g* so that its (*0*, *0*) coordinate is at the top left corner of the game rectangle. Then we draw the result of the current move (line 52) by calling the *draw* method from *TreasureHunt* with *hunt*, passing the *Graphics* object *g* and the mouse location within the playing rectangle.

Finally, the *PlayTreasureHunt* class, shown in **Example 16.14**, includes the *main* method to create a

TreasureHuntViewController application showing a *TreasureHunt* game. **Figures 16.17** and **16.18** show the program running. In Figure 16.17, the user is getting close to the treasure, and in Figure 16.18, the user has found the treasure.

Example 16.14 The *PlayTreasureHunt* Class

```
/* PlayTreasureHunt class
*  Anderson, Franceschi
*/

import javax.swing.JFrame;

public class PlayTreasureHunt
{

Description

Figure 16.18 The User Has Found the Treasure

Description

In both the sub hunt and treasure hunt examples, the Model is reusable in another application. However, the View and the Controller are combined in the same class, and are not reusable. Later in the chapter, we will make the View reusable too.

16.12 Layout Managers: *GridLayout*

We have been using the *FlowLayout* layout manager because it is the easiest to use. The *FlowLayout* layout manager adds new components from left to right, creating as many rows as needed. A problem, however, is that if the user resizes the window, the components are rearranged to fit the new window size. Typically, GUIs can be quite complex and use many components, all of which need to be organized so that the user interface is effective and easy to use even if the user resizes the window. Two useful layout managers that give us more control over the organization of components within a window are the *GridLayout* and the *BorderLayout*.

Regardless of the layout manager used, the constructor of our application will still perform the following setup operations:

- declare and instantiate the layout manager
- use the *setLayout* method of the *Container* class to set the

layout manager of the content pane of the *JFrame*
- instantiate components
- add components to the content pane using one of the *add* methods of the *Container* class

The *GridLayout* organizes the container as a grid. We can visualize the layout as a table made up of equally sized cells in rows and columns. Each cell can contain one component. The first component added to the container is placed in the first column of the first row; the second component is placed in the second column of the first row, and so on. When all the cells in a row are filled, the next component added is placed in the first cell of the next row.

Table 16.23 shows two constructors of the *GridLayout* class.

GridLayout Constructors

<table>
<tr><th colspan="2">Constructors</th></tr>
<tr><th>Class</th><th>Constructor</th></tr>
<tr><td><code>GridLayout</code></td><td><code>GridLayout(int numberOfRows, int numberOfColumns)</code></td></tr>
<tr><td colspan="2">creates a grid layout with the number of rows and columns specified by the arguments.</td></tr>
<tr><td><code>GridLayout</code></td><td><code>GridLayout(int numberOfRows, int numberOfColumns, int hGap, int vGap)</code></td></tr>
<tr><td colspan="2">creates a grid layout with the specified number of rows and columns and with a horizontal gap of <i>hGap</i> pixels between columns and a vertical gap of <i>vGap</i> pixels between rows. Horizontal gaps are also placed at the left and right edges, and vertical gaps are placed at the top and bottom edges.</td></tr>
</table>

Description

In order to focus on how to use a *GridLayout*, we keep the next example as simple as possible and do not use the MVC architecture. **Example 16.15** shows how to use a *GridLayout* to display a chessboard. Each square's position on a chessboard can be identified by a letter and a number. From the standpoint of the white player, the lower right square is h1, and from the standpoint of the black player, the lower right square is a8. When the user clicks on a square on the chessboard, our application displays its position. We show the chessboard oriented as if the white player is on the left and the black player is on the right.

Example 16.15 The *ChessBoard* Class

```
/* Using GridLayout to organize our window
   Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class ChessBoard extends JFrame
{
 private Container contents;
 private JButton [ ][ ] squares;
 private String [ ] letters =
    { "a", "b", "c", "d", "e", "f", "g", "h" };
 private int [ ] digits = { 1, 2, 3, 4, 5, 6, 7, 8 };

 public ChessBoard( )
 {
  super( "Click a square to reveal its position" );
  contents = getContentPane( );

  // set layout to an 8-by-8 Grid
  contents.setLayout( new GridLayout( letters.length, digits.length ) );

  squares = new JButton[letters.length][digits.length];

  ButtonHandler bh = new ButtonHandler( );

  for ( int i = 0; i < letters.length; i++ )
  {
   for ( int j = 0; j < digits.length; j++ )
   {
    // instantiate JButton array
    squares[i][j] = new JButton( );

    // make every other square red
    if ( ( i + j ) % 2 == 0 )
      squares[i][j].setBackground( Color.RED );

    // add the JButton
    contents.add( squares[i][j] );

    // register listener on button
    squares[i][j].addActionListener( bh );
   }
  }

  setSize( 400, 400 );
  setVisible( true );
 }

 private class ButtonHandler implements ActionListener
 {
  public void actionPerformed( ActionEvent ae )
  {
    for ( int i = 0; i < letters.length; i++ )
    {
      for ( int j = 0; j < digits.length; j++ )
      {
        if ( ae.getSource( ) == squares[i][j] )
        {
          squares[i][j].setText( letters[i] + digits[j] );
          return;
        }
      }
    }
  }
 }

 public static void main( String [ ] args )
 {
   ChessBoard myGame = new ChessBoard( );
   myGame.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

A two-dimensional array of *JButtons*, named *squares* (line 12), make up the chessboard. We use two arrays, one of *Strings*, named *letters*, and one of *ints*, named *digits*, to make up the position of each square (lines 13–15). The position of a square is composed of a letter representing the row (a–h) and a number representing the column (1–8). When the user clicks on a button of the chessboard, we set the text of that button to display its position on the board, composing the name from the data in the arrays *letters* and *digits*.

At line 23, we instantiate a *GridLayout* anonymous object using the constructor with two arguments representing the number of rows and columns in the grid, here the number of elements of the *letters* array and the number of elements of the *digits* array. Still at line 23, we pass the *GridLayout* anonymous object as the argument of the *setLayout* method. Thus, components will be added cell-by-cell to an 8-by-8 grid, with each row being filled before starting the next row.

At line 27, we declare and instantiate the listener *bh*, a *ButtonHandler* object reference. Since we are interested in events related to buttons, our *Button-Handler private* inner class *implements* the *ActionListener* interface and overrides the *actionPerformed* method. At line 25, we instantiate the two-dimensional array *squares*. Because we have a two-dimensional array of *JButtons*, we use nested *for* loops at lines 29–46 to instantiate the *JButtons*, add them to the content pane, and register the listener on all of the buttons. Inside the inner loop, the value of the expression *(i + j)* will alternate between an even and odd number. Accordingly, at lines 36–38, we set the background color of every other button to red.

In the *actionPerformed* method, we use nested *for* loops at lines 56–66 to identify the source of the event, that is, which button the user clicked. We then set the text of that button to its board position (line 62), using the corresponding elements in the two arrays *letters* and *digits*. Having found the source of the event, we then exit the event handler via the *return* statement (line 63) to interrupt the *for* loops, and thus avoid unnecessary processing.

Figure 16.19 shows the example running. When you run this program, click on various squares; resize the window, and check that the layout manager maintains an 8-by-8 grid.

Figure 16.19 Running Example 16.15

Description

Layout managers can be set dynamically, based on user input. For example, the user could enter the number of rows or columns of the grid. Or based on user input, we can rearrange the components using another layout manager, such as *FlowLayout*. The user could also instruct us to remove components and add others. Our next example, the Tile Puzzle game, will illustrate some of these capabilities.

In the Tile Puzzle game, eight tiles displaying the digits 1 through 8 are scrambled on a 3-by-3 grid, leaving one cell empty. Any tile adjacent to the empty cell can be moved to the empty cell by clicking on the numbered tile. The goal is to rearrange the tiles so that the numbers are in the correct order, as shown in **Figure 16.20**.

Figure 16.20 The Winning Position of a 3-by-3 Tile Puzzle Game

Description

The Tile Puzzle game can also be played on a 4-by-4, a 5-by-5, and more generally, an *n*-by-*n* grid. We will set up a 3-by-3 grid for the first game, then will randomly select a 3-by-3, a 4-by-4, a 5-by-5, or a 6-by-6 grid for subsequent games. Once you understand this example, you can modify it to allow the user to specify the size of the grid.

Before designing the GUI class, we first code the Model, a class to encapsulate the functionality of the tile puzzle game; the *TilePuzzle* class (**Example 16.16**) handles the creation of a game of a given size, enables play, and enforces the rules of the game.

Example 16.16 The *TilePuzzle* Class

```java
/* TilePuzzle class
*  Anderson, Franceschi
*/

public class TilePuzzle
{
 private String [ ][ ] tiles;
 private int side; // grid size
 private int emptyRow;
 private int emptyCol;

 /** constructor
 *  @param  newSide  grid size
 */
 public TilePuzzle( int newSide )
 {
  setUpGame( newSide );
 }

 /** setUpGame
 *  @param  newSide   grid size
 */
 public void setUpGame( int newSide )
 {
    if ( newSide < 1 )
      side = 3;
    else
      side = newSide;
    emptyRow = side - 1;
    emptyCol = side - 1;
    tiles = new String[side][side];

  // initialize tiles
  for ( int i = 0; i < side; i++ )
  {
   for ( int j = 0; j < side; j++ )
   {
     tiles[i][j] = String.valueOf( ( side * side )
                            - ( side * i + j + 1 ) );
   }
  }
  // set empty cell label to blank
  tiles[side - 1][side - 1] = "";
 }

 /** getSide
 *  @return side
 */
 public int getSide( )
 {
   return side;
 }

 /** getTiles
 *  @return a copy of tiles
 */
 public String [ ][ ]  getTiles( )
 {
  String[ ][ ] copyOfTiles = new String[side][side] ;

  for ( int i = 0; i < side; i++ )
  {
   for ( int j = 0; j < side; j++ )
   {
     copyOfTiles[i][j] = tiles[i][j];
   }
  }
  return copyOfTiles;
 }

 /** tryToPlay
 *  enable play if play is legal
 *  @return true if the play is legal, false otherwise
 */
 public boolean tryToPlay( int row, int col )
 {
  if ( possibleToPlay( row, col ) )
  {
   // play: switch empty String and tile label at row, col
   tiles[emptyRow][emptyCol] = tiles[row][col];
   tiles[row][col] =  "";
   // update emptyRow and emptyCol
   emptyRow = row;
   emptyCol = col;
   return true;
  }
  else
   return false;
 }

 /** possibleToPlay
 *  @return true if the play is legal, false otherwise
 */
 public boolean possibleToPlay( int row, int col )
 {
  if ( ( col == emptyCol && Math.abs( row - emptyRow ) == 1 )
         || ( row == emptyRow && Math.abs( col - emptyCol ) == 1 ) )
    return true;
  else
    return false;
 }

 /** won
 *  @return true if the tiles are all at the right place, false otherwise
 */
 public boolean won( )
 {
  for ( int i = 0; i < side ; i++ )
  {
   for ( int j = 0; j < side; j++ )
   {
     if ( !( tiles[i][j].equals(
                       String.valueOf( i * side + j + 1 ) ) )
                       && ( i != side - 1 || j != side - 1 )  )
       return false;
   }
  }
  return true;
 }
}
```

Description

The instance variable *tiles* (line 7), a two-dimensional array of *Strings*, stores the state of the puzzle. Each element of *tiles* will be a cell in the puzzle grid. The instance variable *side*, declared at line 8, represents the size of the grid. The instance variables *emptyRow* and *emptyCol*, declared at lines 9–10, identify the empty cell in the puzzle grid.

The constructor (lines 12–18) calls the *setUpGame* method (lines 20–44), passing the size of the grid (*newSide*) as an argument. We also call the *setUpGame* method before starting each new game in the GUI class.

Inside the *setUpGame* method, we assign *newSide* to *side*. Rather than randomly generating each tile label, which would complicate this example, we assign the labels to the tiles in descending order using nested *for* loops (lines 33–41). We set the empty cell to the last cell in the grid at lines 42–43.

The *tryToPlay* method (lines 71–89) first checks if the play is legal by calling the *possibleToPlay* method (line 77). If the *possibleToPlay* method returns *true*, we proceed with the play and return *true*; otherwise, we return *false*. Playing means swapping the values of the empty cell (*emptyRow*, *emptyCol*) and the cell that was just played, represented by the two parameters of *tryToPlay*, *row*, and *col*.

The *possibleToPlay* method is coded at lines 91–101. If the play is legal—that is, if the tile played is within one cell of the empty cell—the method returns *true*; otherwise, the method returns *false*.

The *won* method (lines 103–119) checks if the tiles are in order. If so, the *won* method returns *true*; otherwise, the method returns *false*.

As in the chessboard example, when the user clicks on a button, we need to identify the row and the column of that button. In order to avoid looping through all the buttons, we create a class that *extends* the *JButton* class and add two instance variables for the row and column indexes. In this way, when a button belonging to a two-dimensional array of buttons is clicked, we can access its row and column instance variables in order to retrieve its row and column indexes within the array.

Example 16.17 shows the *GridButton* class, which extends the *JButton* class and adds two instance variables, *row* and *column* (lines 9–10). The constructor at lines 12–22 allows the client to create a *GridButton* object at a specified row and column. Note that this class is not specific to the tile puzzle application and can be reused for other applications involving an array of buttons placed on a grid.

Example 16.17 The *GridButton* Class

```java
/** GridButton class
*   Anderson, Franceschi
*/

import javax.swing.JButton;

public class GridButton extends JButton
{
 private int row;
 private int column;

 /** Constructor
 * @param title
 * @param newRow row
 * @param newColumn column
 */
 public GridButton( String title, int newRow, int newColumn )
 {
  super( title );
  setRow( newRow );
  setColumn( newColumn );
 }

 /** getRow method, accessor for row
 * @return row
 */
 public int getRow( )
 {
   return row;
 }

 /** getColumn method, accessor for column
 * @return column
 */
 public int getColumn( )
 {
   return column;
 }

 /** setRow method, mutator for row
 * @param newRow, an int
 */
 public void setRow( int newRow )
 {
   if ( newRow >= 0 )
     row = newRow;
 }

 /** setColumn method
 * @param newColumn, an int
 */
 public void setColumn( int newColumn )
 {
   if ( newColumn >= 0 )
     column = newColumn;
 }
}
```

Description

Figure 16.21 shows the UML diagram for the *TilePuzzle* and *TilePuzzleViewController* classes.

Figure 16.21 UML Diagram for *TilePuzzle* and *TilePuzzleViewController*

Description

Example 16.18 shows the *TilePuzzleViewController* class; again, it combines the View and the Controller.

Example 16.18 The *TilePuzzleViewController* Class

```
/** Using GridLayout dynamically
*   Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;
import java.util.Random;

public class TilePuzzleViewController extends JFrame
{
 private Container contents;

 private GridButton [ ][ ] squares;
 private TilePuzzle game; // the tile puzzle game

 public TilePuzzleViewController( TilePuzzle newGame )
 {
  super( "The Tile Puzzle Game" );
  game = newGame;
  setUpGameGUI( );
 }

 public void setUpGameGUI( )
 {
  contents = getContentPane( );
  contents.removeAll( ); // remove all components
  contents.setLayout( new GridLayout( game.getSide( ),
                                      game.getSide( ) ) );
  squares = new GridButton [game.getSide( )][game.getSide( )];

  ButtonHandler bh = new ButtonHandler( );

  // for each button: instantiate button with appropriate button label,
  // add to container, and register listener
  for ( int i = 0; i < game.getSide( ); i++ )
  {
   for ( int j = 0; j < game.getSide( ); j++ )
   {
    squares[i][j] = new GridButton( game.getTiles( )[i][j], i, j );
    contents.add( squares[i][j] );
    squares[i][j].addActionListener( bh );
   }
  }

  setVisible( true );
 }

 public void update( )
 {
  for ( int i = 0; i < game.getSide( ); i++ )
  {
   for ( int j = 0; j < game.getSide( ); j++ )
   {
    squares[i][j].setText( game.getTiles( )[i][j] );
   }
  }

  if ( game.won( ) )
  {
   JOptionPane.showMessageDialog( TilePuzzleViewController.this,
         "Congratulations! You won!\nSetting up new game" );
   Random random = new Random( );
   int sideOfPuzzle = 3 + random.nextInt( 4 );
   game.setUpGame( sideOfPuzzle );
   setUpGameGUI( );
  }
 }

 private class ButtonHandler implements ActionListener
 {
  public void actionPerformed( ActionEvent ae )
  {
   GridButton button = ( GridButton ) ae.getSource( );
   if ( game.tryToPlay( button.getRow( ), button.getColumn( ) ) )
     update( );
  }
 }
}
```

Description

Each tile in the game is a *GridButton*. The instance variable *squares* (line 14) will hold a two-dimensional array of *GridButtons* so that each element of *squares* will be a cell in the game grid. The *TilePuzzle* instance variable *game*, declared at line 15, represents the Model, the tile puzzle game that we will display inside the window. When the user plays, we will call the various methods of the *TilePuzzle* class to enforce the rules of the game.

The constructor (lines 17–22) instantiates *game* and calls the *setUpGameGUI* method. The constructor and the *setUpGameGUI* method define the View. The *private* class *ButtonHandler* (lines 70–78) and the *update* method (lines 49–68) make up the Controller.

The *setUpGameGUI* method (lines 24–44) displays the game in its starting position. We first remove all the components from the content pane by calling the *removeAll* method of the *Container* class (line 27) and set the layout manager (lines 28–29) as a *GridLayout* with a grid size equal to the *side* instance variable of *game*. We instantiate the *squares* array and our event handler at lines 30 and 32. After that, we use nested *for* loops (lines 34–44) to instantiate each button, add it to the container, and register the event handler. The *squares* array parallels the *tiles* array of the *TilePuzzle* class; the *squares* buttons are labeled with the values of *tiles*.

When a button is clicked, our *ButtonHandler actionPerformed* method is executed. To determine which button was clicked, we call the *getSource* method using the *ActionEvent* event object that was sent to the method (line 74). We then need to determine whether the button clicked was a legal play. To do this, we call the *tryToPlay* method at line 75 with the row and column instance variable values of the button. If that method returns *true*, the play was legal and the model has changed (i.e., a tile has been moved). We then call the *update* method to make the view (i.e., the buttons) reflect the model (line 76).

The *update* method first updates the *squares* button array (lines 51–57). We then test if the current move solved the puzzle by calling the *won* method (line 59) of the *TilePuzzle* class. If the *won* method returns *true*, we congratulate the user by popping up a dialog box at lines 61–62. Note that we use *TilePuzzleViewController.this* as the parent component in the *showMessageDialog* method. This makes the dialog appear in the center of our application window.

We then randomly generate a grid size between three and six (lines 63–64) for the next game and call the *setUpGame* method (line 65) and the *setUpGameGUI* method (line 66) to begin a new game with the new grid size.

Finally, the *PlayTilePuzzle* class, shown in **Example 16.19**, includes the *main* method to create a *TilePuzzleViewController* application showing a *TilePuzzle* game. **Figure 16.22** shows a run of this game after the user has moved some tiles.

Example 16.19 The *PlayTilePuzzle* Class

```java
/** PlayTilePuzzle class
*     Anderson, Franceschi
*/

import javax.swing.JFrame;

public class PlayTilePuzzle extends JFrame
{
 public static void main( String [ ] args )
 {
  TilePuzzle puzzle = new TilePuzzle( 3 );
  TilePuzzleViewController puzzleGui
    = new TilePuzzleViewController( puzzle );
  puzzleGui.setSize( 300, 300 );
  puzzleGui.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

16.13 Layout Managers: *BorderLayout*

A *BorderLayout* organizes a container into five areas: north, south, west, east, and center, with each area holding at most one component. Thus, for each area, you can add one component or no component. The size of each area expands or contracts depending on the size of the component in that area, the sizes of the components in the other areas, and whether the other areas contain a component. **Figure 16.23** shows the areas in a sample border layout.

Figure 16.23 *BorderLayout* Areas

Description

In contrast to the *FlowLayout* and *GridLayout* layout managers, the order in which we add components to a *BorderLayout* is not important. We use a second argument in the *add* method to specify the area in which to place the component. This *add* method of the *Container* class has the API shown in **Table 16.24**.

The *Container add* Method for Using a *BorderLayout*

Return Value	**Method Name and Argument List**
`void`	`add( Component c, Object borderlayoutArea )` adds the component *c* to the container. The area defined by *borderlayoutArea* can be specified using any of the following *static String* constants in the *BorderLayout* class: *NORTH, SOUTH, EAST, WEST, CENTER.*

Description

Two *BorderLayout* constructors are shown in **Table 16.25.** The *BorderLayout* is the default layout for a *JFrame* class, so if we want to use a border layout for our GUI application, we do not need to instantiate a new layout manager.

BorderLayout Constructors

Constructors

Class	**Constructor**
`BorderLayout`	`BorderLayout( )` creates a new border layout with no gaps between components.
`BorderLayout`	`BorderLayout( int hGap, int vGap )` creates a border layout with a horizontal gap of *hGap* pixels between components and a vertical gap of *vGap* pixels between components. Unlike *GridLayout*, horizontal gaps are not placed at the left and right edges, and vertical gaps are not placed at the top and bottom edges.

Description

Our next example uses a *BorderLayout* to illustrate how we can mix red, green, and blue colors to create a new color. We place buttons in the west, south, and east positions to represent the colors red, green, and blue. We place a label in the center position to show the color being made. Color values are between 0 and 255. When the user clicks on one of the buttons, we change the corresponding amount of that color by a specified increment. For example, if the amount of red is 100 and the incremental amount is 10, and the user clicks on the Red button, the value of red will become 110.

In the north position, we place a button "Change Direction," which will make the incremental amount toggle between a positive and a negative value; for example, if the incremental amount is 10 and the user clicks the button, the incremental amount becomes −10.

In this example, we use the MVC architecture and we separate the View from the Controller, thus making the View class reusable, in addition to the Model. **Figure 16.24** shows the UML diagram for *RGBColorMixer* (the Model), *BorderLayoutView* (the View), and *RGBColorMixerController* (the Controller).

Figure 16.24 The UML Diagram for Classes of This Application

Description

We first code our Model, the *RGBColorMixer* class (**Example 16.20**), a class that encapsulates the making of a color based on the RGB system by changing one color component at a time by a given increment. This class is a standalone class and can be reused in another application in a different context. The instance variable *color* (line 15), a *Color*, stores the color that we are making. The instance variable *delta* (line 14), an *int*, stores the amount by which a color component of *color* can be incremented or decremented at a time; *delta* can be either positive or negative. The value of a color component is between *0* and *255* included, so we only allow values between –*255* and *255* for *delta* (line 22). If *delta* is positive, the starting color is black (*0*, *0*, *0*), and if *delta* is negative, the starting color is white (*255*, *255*, *255*) (lines 26–29).

Example 16.20 The *RGBColorMixer* Class

```java
/** RGBColorMixer class
*   Anderson, Franceschi
*/

import java.awt.Color;

public class RGBColorMixer
{
 public static int POSITION_CHANGE = 0;
 public static int POSITION_RED = 1;
 public static int POSITION_GREEN = 2;
 public static int POSITION_BLUE = 3;

 private int delta; // color increment
 private Color color; // mixed color

 /** Constructor
 * @param newDelta delta
 */
 public RGBColorMixer( int newDelta )
 {
  if ( newDelta < -255 || newDelta > 255 || newDelta == 0 )
    delta = 1;
  else
    delta = newDelta;
  if ( delta > 0 )
    color = Color.BLACK;
  else
    color = Color.WHITE;
 }

 /** getColor method
 * @return color
 */
 public Color getColor( )
 {
  return color;
 }

 /** invertDelta method
 * sets delta to its opposite
 */
 public void invertDelta( )
 {
  delta = -delta;
 }

 /** addToRed method
 * add delta to red component of color
 */
 public void addToRed( )
 {
  if ( color.getRed( ) + delta > 255 )
    color = new Color( 255, color.getGreen( ), color.getBlue( ) );
  else if ( color.getRed( ) + delta < 0 )
    color = new Color( 0, color.getGreen( ), color.getBlue( ) );
  else
    color = new Color( color.getRed( ) + delta, color.getGreen( ),
                       color.getBlue( ) );
 }

 /** addToGreen method
 * add delta to green component of color
 */
 public void addToGreen( )
 {
  if ( color.getGreen( ) + delta > 255 )
    color = new Color( color.getRed( ), 255, color.getBlue( ) );
  else if ( color.getGreen( ) + delta < 0 )
    color = new Color( color.getRed( ), 0, color.getBlue( ) );
  else
    color = new Color( color.getRed( ), color.getGreen( ) + delta,
                       color.getBlue( ) );
 }

 /** addToBlue method
 * add delta to blue component of color
 */
 public void addToBlue( )
 {
  if ( color.getBlue( ) + delta > 255 )
    color = new Color( color.getRed( ), color.getGreen( ), 255 );
  else if ( color.getBlue( ) + delta < 0 )
    color = new Color( color.getRed( ), color.getGreen( ), 0 );
  else
    color = new Color( color.getRed( ), color.getGreen( ),
                       color.getBlue( ) + delta );
 }

  /** getMethodLabel method
 * @param position 0: Change, 1: Red, 2: Green, 3: Blue
 * @return a String to use as the text to label
 *         the calling of one of the methods
 *         invertDelta, addToRed, addToGreen, and addToBlue
 */
 public String getMethodLabel( int position )
 {
  if ( position == POSITION_CHANGE )
    return "CHANGE DIRECTION";
  else if ( position == POSITION_RED )
    return "RED";
  else if ( position == POSITION_GREEN )
    return "GREEN";
  else if ( position == POSITION_BLUE )
    return "BLUE";
  else
    return "";
 }

 /** getTitle method
  * @return a String to use as title for this object
 */
 public String getTitle( )
 {
   return "Start Mixing Colors";
 }

 /** toString method
 * @return a String representation of color
 */
 public String toString( )
 {
  String colorText = color.toString( );
  int bracketIndex = colorText.indexOf( "[" );
  if ( bracketIndex >= 0 )
    colorText = colorText.substring( bracketIndex, colorText.length( ) );
  return colorText;
 }
}
```

Description

The *invertDelta* method (lines 40–46) changes the value of *delta* to its opposite. This will be useful, for example, if delta is positive and any of the color components reaches the maximum value of 255, or if delta is negative and any of the color components reaches the minimum value of 0.

The *addToRed* method (lines 48–60) adds *delta* to the red component of *color*, keeping that value between *0* and *255*. The *addToGreen* and *addToBlue* methods are similar and update the green and blue components of *color*, respectively. These methods call the *getRed*, *getGreen*, and *getBlue* accessor methods of the *Color* class to get the current *int* value of each color component.

The *getMethodLabel* method (lines 90–108) returns a *String* that can be used as a label in a graphical user interface for the methods *invertDelta*, *addToRed*, *addToGreen*, and *addToBlue*. Although we know that we will be using a *BorderLayout* for this application, we design *RGBColorMixer* so that it can be reused with other Views and layouts. Thus, we do not use the *BorderLayout String* constants *NORTH, WEST, SOUTH*, and *EAST* as possible arguments passed to this method. Instead, we provide static constants (lines 9–12) to represent possible changes in *delta* (*POSITION_CHANGE*), the red component of this color (*POSITION_RED*), the green component of this color (*POSITION_GREEN*), and the blue component of this color (*POSITION_BLUE*). These constants can be used when calling the *getMethodLabel* method.

The *getTitle* method (lines 110–116) returns a *String* that can be used as the title of an application using this Model. The *toString* method (lines 118–128) returns a *String* representation of *color*.

Example 16.21 shows the *BorderLayoutView* class, which represents the View for this application. Note that the Controller is not included in this class and this class is generic; it can be used for many other applications.

Example 16.21 The *BorderLayoutView* Class

```
/** BorderLayoutView class
*   Reusable generic frame using a BorderLayout
*   Four buttons occupy the North, East, South, and West positions
*   A label with centered text occupies the center position
*   Accessors are provided so that a Controller can access
*   the four buttons and the label
*   Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;

public class BorderLayoutView extends JFrame
{
 private JButton north, east, south, west;
 private JLabel center;

 public BorderLayoutView( )
 {
  super( );
  Container contents = getContentPane( );
  contents.setLayout( new BorderLayout( ) ); // optional

  // instantiate button objects
  north = new JButton( );
  east = new JButton( );
  south = new JButton( );
  west = new JButton( );

  center = new JLabel( "", SwingConstants.CENTER );
  center.setOpaque( true );

  // order of adding components is not important
  contents.add( north, BorderLayout.NORTH );
  contents.add( east, BorderLayout.EAST );
  contents.add( south, BorderLayout.SOUTH );
  contents.add( west, BorderLayout.WEST );
  contents.add( center, BorderLayout.CENTER );

  setVisible( true );
 }

 public JButton getNorth( )
 {
  return north;
 }

 public JButton getEast( )
 {
  return east;
 }

 public JButton getSouth( )
 {
  return south;
 }

 public JButton getWest( )
 {
  return west;
 }

 public JLabel getCenter( )
 {
  return center;
 }
}
```

Description

We declare four buttons at line 15; we will place one button each in the north, east, south, and west areas of the border layout. We use the label *center*, declared at line 16, to display something in the center area.

At line 22, we set the layout of the content pane to be a *BorderLayout*. Note that this statement is optional, because *BorderLayout* is the default layout manager for a subclass of the *JFrame* class.

When instantiating *center* at lines 30–31, we use an overloaded *JLabel* constructor. We use the *static int* constant *CENTER* of the *SwingConstants* interface to center the text of the label within the component. By default, the text for a *JLabel* is left-aligned. Because the text on a *JButton* is centered by default, we can simply use the constructor with one argument when we instantiate the *JButtons*.

We add the four buttons and the label to the content pane in the appropriate areas at lines 33–38. The order in which we add the components is not important because we specify a border layout area as the second argument of the *add* method.

We also provide accessor methods for the four buttons and the label so that they can be updated from outside the class.

Note that the Model and the View are completely independent and can be reused separately in other applications.

Example 16.22 shows the *RGBColorMixerController* class, which is the Controller for this application. At lines 10–11, we declare *model*, an *RGBColorMixer* instance variable, and *view*, a *BorderLayoutView*, our two instance variables. They enable us to get user input from the View, call the various methods of the Model (the *RGBColorMixer* class), and update the View.

Example 16.22 The *RGBColorMixerController* Class

```
/** RGBColorMixerController class
*   Anderson, Franceschi
*/

import java.awt.event.*;
import javax.swing.*;

public class RGBColorMixerController implements ActionListener
{
 private RGBColorMixer model;
 private BorderLayoutView view;

 public RGBColorMixerController( RGBColorMixer newModel,
        BorderLayoutView newView )
 {
  model = newModel;
  view = newView;

  view.setTitle( model.getTitle( ) );

  JButton north = view.getNorth( ), west = view.getWest( ),
          south = view.getSouth( ), east = view.getEast( );

  north.setText( model.getMethodLabel( RGBColorMixer.POSITION_CHANGE ) );
  west.setText( model.getMethodLabel( RGBColorMixer.POSITION_RED ) );
  south.setText( model.getMethodLabel( RGBColorMixer.POSITION_GREEN ) );
  east.setText( model.getMethodLabel( RGBColorMixer.POSITION_BLUE ) );

  north.addActionListener( this );
  west.addActionListener( this );
  south.addActionListener( this );
  east.addActionListener( this );

  updateView( );
 }

 public void actionPerformed( ActionEvent ae )
 {
  // update the model
  if ( ae.getSource( ) == view.getNorth( ) )
    model.invertDelta( );
  else if ( ae.getSource( ) == view.getWest( ) )
    model.addToRed( );
  else if ( ae.getSource( ) == view.getSouth( ) )
    model.addToGreen( );
  else if ( ae.getSource( ) == view.getEast( ) )
    model.addToBlue( );
  // update the view
  updateView( );
 }

 /** updateView method
 * updates the color and the text of the center label
 */
 public void updateView( )
 {
  JLabel label = view.getCenter( );
  label.setBackground( model.getColor( ) );
  label.setText( model.toString( ) );
 }
}
```

Description

The constructor (lines 13–35) accepts two parameters that it assigns to *model* and *view*. It sets the title of the frame at line 19, retrieving it from the Model. We use the north button to invert the value of *delta* in *model*, and the west, south, and east buttons to change the red, green, and blue components of *color* in *model*, respectively. Thus, we label the four buttons of the View at lines 24–27 by calling the *getMethodLabel* method with *model*, passing the appropriate position argument. We set up event handling at lines 29–32, registering *this* object (*RGBColorMixerController implements ActionListener*) on the four buttons of the View.

In our *actionPerformed* method (lines 37–50), we need to update the Model and the View. To update *model*, we call the appropriate method of *RGBColorMixer*, depending on which button was clicked. For example, if the west button was clicked, we call *addToRed* (line 43). At lines 48–49, we update the View by calling *updateView*.

In our *updateView* method (lines 52–60), we update the label located in the center of the View, changing its color to the color of *model*, and changing its text to the *String* representation of the Model.

Finally, the *MixColors* class, shown in **Example 16.23**, includes the *main* method to create a color mixing application. Note that we set the size of the View inside *main*, so that we do not have hard-coded dimensions inside the View and Controller classes. **Figure 16.25** shows a run of this example, after the user has clicked on the various buttons a few times.

Example 16.23 The *MixColors* Class

```
/** MixColors class
*   Anderson, Franceschi
*/

import javax.swing.JFrame;

public class MixColors
{
 public static void main( String [ ] args )
 {
  // Instantiate the Model
  RGBColorMixer colorMixer = new RGBColorMixer( -10 );
  // Instantiate the View
  BorderLayoutView colorMixerGui = new BorderLayoutView( );
  colorMixerGui.setSize( 350, 250 );
  colorMixerGui.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
  // Instantiate the Controller
  RGBColorMixerController controller
    = new RGBColorMixerController( colorMixer, colorMixerGui );
 }
}
```

16.14 Using Panels to Nest Components

Components can be nested. Indeed, since the *JComponent* class is a subclass of the *Container* class, a *JComponent* object is a *Container* object as well. As such, it can contain other components. We can use this feature to achieve more precise layouts.

The *JPanel* class is a general-purpose container, or a **panel**, and is typically used to hold other components. When nesting components, we usually place several components into a panel, and place the panel into the content pane of the current *JFrame*. Each panel has its own layout manager, which can vary from panel to panel, and the content pane for the *JFrame* application has its own layout manager, which can be different from any of the panels. We can even have multiple levels of nesting, as needed.

In this example, using three colors (red, green, and blue), we randomly generate an 8-by-8 grid of colors. The user tries to guess the most frequently occurring color by clicking on one of the buttons.

Figure 16.26a shows our window when the application begins, and **Figure 16.26b** shows the underlying layout of the window. We use a *BorderLayout* for the content panel and two

JPanels, each of which has a *GridLayout*. In the west position, we have a *JPanel* containing three buttons in a *GridLayout* having three rows and one column.

Figure 16.26a Running the *MixColors* Application

Description

Figure 16.26b The Underlying Nested Layout

Description

In the center position, we have defined another *JPanel* containing 64 labels managed by a *GridLayout* having eight rows and eight columns. We have not put any components in the north, south, or east areas of the *BorderLayout;* thus, the two areas we are using, west and center, adjust to fill the space.

Again, we use the MVC architecture and design our classes for reusability. This time, we also code the Controller so that it is reusable under certain conditions. Inside the *Controller* class, instead of using a class for the Model, we use an interface. Thus, the Controller is now reusable, along with the same View, with any Model that implements that interface. Note that we could also make the View an interface, but in order to keep this example relatively simple, we do not. To achieve reusability for the Controller, we use the following pattern for the *Controller* class:

```
public class Controller
{
 private ModelInterface model; // ModelInterface is an interface
 private View view;
 …
```

Description

The *ModelInterface* specifies several methods to be implemented that the Controller will call to manage the game. The *Model* class uses this pattern:

```
public class Model implements ModelInterface
{
 // Implements ModelInterface methods
 …
```

Description

We want the *Controller* class to be reusable with any class whose functionality is based on the user clicking buttons on the left panel with a grid of labels in the center position. We could use this class in an application where the user tries to guess the most frequent color, or the least frequent color, or with a different color system (such as HSL – Hue, Saturation, and Lightness), or the most frequent letter or number. Figure 16.27 shows the UML for the interface and classes involved in this example.

Figure 16.27 The UML diagram for the Various Classes and Interface of This Application

Description

Thus, we design an interface to support this type of application. **Example 16.24** shows the *ColorGridGame* interface. It specifies methods to retrieve the title for the grid, its size, its number of colors, the label of a color, the color index of a label (it is implied that the colors used in the grid of colors will come from an array of colors, and that there will be an array of *Strings* (labels) that parallels that array of colors), to test if an answer is the correct answer, and to access each color in the grid. We call these methods from the Controller class with the Model instance variable in order to manage the game.

Example 16.24 The *ColorGridGame* Interface

```
/* ColorGridGame interface
   Anderson, Franceschi
 */

import java.awt.Color;

public interface ColorGridGame
{
 public String getTitle( );
 public int getSize( );
 public int getNumberOfColors( );
 public String getLabel( int index );
 public int getIndex( String label );
 public boolean isCorrect( int index );
 public Color getGridColor( int row, int col );
}
```

Description

We now code our Model for the color frequency game. In this application, we generate colors for our grid of labels.

Example 16.25 shows the *ColorFrequencyGame* class, which *implements ColorGridGame* (line 8). Its *gridColors* instance variable (line 11) stores a two-dimensional array, or grid, of colors. The *coloringColors* and *counts* arrays (lines 12–13) are parallel arrays: *coloringColors* stores the colors used for coloring the grid, and *counts* stores the frequency of each color. The instance variable *labels* (line 15) is an array of *Strings* that also parallels the *coloringColors* array; it is meant to be used as labels for the buttons.

Example 16.25 The *ColorFrequencyGame* Class

```java
/** ColorFrequencyGame class
   Anderson, Franceschi
*/

import java.util.Random;
import java.awt.Color;

public class ColorFrequencyGame implements ColorGridGame
{
 private final int DEFAULT_SIZE = 8;
 private Color [ ][ ] gridColors;
 private Color [ ] coloringColors;
 private int [ ] counts; // color frequencies in gridColors

 private String [ ] labels;

 /** Constructor
 * @param size number of rows and columns in gridColors
 * @param colors coloringColors
 * @param newLabels labels
 */
 public ColorFrequencyGame( int size, Color [ ] colors,
                            String [ ] newLabels )
 {
  if ( size <= 0 )
    size = DEFAULT_SIZE;
  gridColors = new Color[size][size];
  coloringColors = colors;
  counts = new int[coloringColors.length];
  fillGridWithColors( );
  labels = newLabels;
 }

 /** fillGridWithColors method
 * randomly fills gridColors with colors from coloringColors
 */
 public void fillGridWithColors( )
 {
  Random random = new Random( );
  for ( int i = 0; i < gridColors.length; i++ )
  {
   for ( int j = 0; j < gridColors[i].length; j++ )
   {
    int colorIndex = random.nextInt( coloringColors.length );
    gridColors[i][j] = coloringColors[colorIndex];
    counts[colorIndex] += 1;
   }
  }
 }

 /** getSize method
 * @return length of gridColors
 */
 public int getSize( )
 {
  return gridColors.length;
 }

 /** getNumberOfColors method
 * @return length of coloringColors
 */
 public int getNumberOfColors( )
 {
  return coloringColors.length;
 }

 /** getGridColor method
 * @param row, an int, the row index
 * @param col, an int, the column index
 * @return gridColor[row][col]
 */
 public Color getGridColor( int row, int col )
 {
  return gridColors[row][col];
 }

 /** highestCount method
 * @return the highest color frequency in the grid
 */
 public int highestCount( )
 {
  int max = counts[0];
  for ( int i = 1; i < counts.length; i++ )
  {
   if ( counts[i] > max )
     max = counts[i];
  }
  return max;
 }

 /** isCorrect method
 * @param index, an int
 * @return true if the frequency of the color for index
 *         is the highest, false otherwise
 */
 public boolean isCorrect( int index )
 {
  return counts[index] == highestCount( );
 }

 /** getTitle method
 * @return a String representing a title for this object
 */
 public String getTitle( )
 {
  return "What is the most frequent color?";
 }

 /** getLabel method
 * @param index, an int
 * @return labels[index]
 */
 public String getLabel( int index )
 {
  return labels[index];
 }

 /** getIndex method
 * @param label, a String
 * @return index of label in labels
 */
 public int getIndex( String label )
 {
  for ( int i = 0; i < labels.length; i++ )
  {
   if ( labels[i].equals( label ) )
     return i;
  }
  return -1;
 }
}
```

Description

The constructor (lines 17–32) instantiates all three arrays and calls the *fillGridWithColors* method at line 30. The *fillGridWithColors* method (lines 34–49) fills the grid of colors with colors randomly generated from the *coloringColors* array and keeps track of their respective frequency in the *counts* array (line 46).

To determine whether the user has chosen the correct color, we provide the *isCorrect* method (lines 91–99) that takes as a parameter the index of the selected color. It returns *true* if the value in *counts* at that index is maximal, *false* otherwise. The *highestCount* method (lines 77–89) calculates and returns the maximum value in the *counts* array.

The *getLabel* method (lines 109–116) returns the element of the array *labels* at an index, the parameter of the method; that is, the label to be used with a color located at that index within the array *coloringColors*. The *getIndex* method (lines 118–130) is the opposite method: It returns the index within the array *labels* of a *String*, the parameter of the method; the color corresponding to that label is the element in the array *coloringColors* at that index.

Example 16.26 shows the *BorderedLabelGridView* class. It is managed by a *BorderLayout*, which contains two *JPanels*, one in the west and one in the center position. The other positions within the *BorderLayout* are not used. The west panel contains an array of buttons, arranged vertically, managed by a *GridLayout*, and the center panel contains a grid of labels, managed by another *GridLayout*. Thus, our instance variables are two panels, an array of buttons, and a two-dimensional array of labels (lines 17–20).

Example 16.26 The *BorderedLabelGridView* Class

```
/** BorderedLabelGridView class
*   Reusable generic frame using a BorderLayout
*   containing the west and center panels
*   The west panel is made up of a vertical array of buttons
*   The center panel is made up of a grid of labels
*   Accessors are provided so that a Controller can access
*   the array of buttons and the 2-dim array (grid) of labels
*   Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.ActionListener;

public class BorderedLabelGridView extends JFrame
{
 private JPanel buttonPanel; // left, holds array of buttons
 private JButton[ ] buttons;
 private JPanel grid; // center, holds grid of labels
 private JLabel[ ][ ] labels; // grid of labels

 public BorderedLabelGridView( int numberOfButtons, int gridSize )
 {
  super( );

  Container contents = getContentPane( );
  contents.setLayout( new BorderLayout( ) );

  grid = new JPanel( );
  GridLayout gameGrid = new GridLayout( gridSize, gridSize );
  grid.setLayout( gameGrid );

  labels = new JLabel[gridSize][gridSize];
  for ( int i = 0; i < labels.length; i++ )
  {
    for ( int j = 0; j < labels[i].length; j++ )
    {
     labels[i][j] = new JLabel( );
     labels[i][j].setOpaque( true );
     grid.add( labels[i][j] );
    }
  }

  buttonPanel = new JPanel( );
  GridLayout buttonGrid = new GridLayout( numberOfButtons, 1 );
  buttonPanel.setLayout( buttonGrid );

  buttons = new JButton[numberOfButtons];
  for ( int i = 0; i < buttons.length; i++ )
  {
    buttons[i] = new JButton( );
    buttonPanel.add( buttons[i] );
  }

  contents.add( BorderLayout.WEST, buttonPanel );
  contents.add( BorderLayout.CENTER, grid );
  setVisible( true );
 }

 public void setButtonText( int row, String text )
 {
  buttons[row].setText( text );
 }

 public void setButtonListener( int row, ActionListener al )
 {
  buttons[row].addActionListener( al );
 }

 public void setLabelBackground( int row, int col, Color color )
 {
  labels[row][col].setBackground( color );
 }
}
```

Description

We first define the layout manager for our content panel to be a *BorderLayout* at line 27. Then we set up the panel for the center position at lines 29–31, by instantiating the *JPanel* instance variable named *grid* and setting its layout manager as a *GridLayout* using the constructor parameter *gridSize* for the number of rows and columns. At lines 33–42, we instantiate the labels and add them to the grid.

At lines 44–46, we set up the panel for the west position by instantiating the *JPanel* instance variable named *buttonPanel* and setting its layout manager as a *GridLayout* with *numberOfButtons* rows and one column. At lines 48–53, we instantiate the buttons and add them to *buttonPanel*.

We add *buttonPanel* and *grid* to the content pane at lines 55–56 in the west and center positions, respectively. Finally, we provide accessor methods for the arrays of buttons and labels so that they can be accessed from outside the class.

We also provide methods to set the text and set an *ActionListener* for each button in the array *buttons*, and set the background color of each label in the array *labels*. By calling these methods, the Controller can change the View (based on data from the Model).

Example 16.27 shows the *ColorGridGameController* interface. At lines 11–12, we declare *model*, a *ColorGridGame*, and *view*, a *BorderedLabelGridView*, our two instance variables. They enable us to get user input from the View, call the appropriate methods of the Model, and update the View accordingly.

Example 16.27 The *ColorGridGameController* Class

```java
/** ColorGridGameController class
*   Anderson, Franceschi
*/

import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class ColorGridGameController implements ActionListener
{
 private ColorGridGame model;
 private BorderedLabelGridView view;

 public ColorGridGameController( ColorGridGame newModel,
                                 BorderedLabelGridView newView )
 {
  model = newModel;
  view = newView;
  setUpGame( );
 }

 public void setUpGame( )
 {
  view.setTitle( model.getTitle( ) );
  setUpLabels( );
  setUpButtons( );
 }

 public void setUpLabels( )
 {
  for ( int i = 0; i < model.getSize( ); i++ )
    for ( int j = 0; j < model.getSize( ); j++ )
      view.setLabelBackground( i, j, model.getGridColor( i, j ) );
 }

 public void setUpButtons( )
 {
  for ( int i = 0; i < model.getNumberOfColors( ); i++ )
  {
    view.setButtonText( i, model.getLabel( i ) );
    view.setButtonListener( i, this );
  }
 }

 public void actionPerformed( ActionEvent ae )
 {
  JButton button = ( JButton ) ae.getSource( );
  int index = model.getIndex( button.getText( ) );

  if ( model.isCorrect( index ) )
    JOptionPane.showMessageDialog( view, "You won" );
  else
    JOptionPane.showMessageDialog( view, "Sorry, you lost" );
  // disable buttons here
 }
}
```

Description

The constructor (lines 14–20) accepts two parameters that it assigns to *model* and *view*, and calls the *setUpGame* method at line 19. The *setUpGame* method (lines 22–27) sets the title of the View, then calls the *setUpLabels* and *setUpButtons* methods.

The *setUpLabels* method (lines 29–34) colors the grid of labels in the View using a double loop. At line 33, we set the background color of the current label by calling the *setLabelBackground* method with *view*, passing the row index, column index, and the background color for that label that we retrieve from the Model by calling the *getGridColor* method.

The *setUpButtons* method (lines 36–43) places a label on each button in the View and sets up event handling using a single loop. At line 40, we set the text for the current button, passing its index and the label that we retrieve from the Model by calling the *getLabel* method. At line 41, we register *this* object (i.e., the controller that implements *ActionListener*) on the current button.

We handle the events for the buttons in the *actionPerformed* method at lines 45–55. We first retrieve the button that originated the event by calling *getSource* at line 47. The *getSource* method returns an *Object*, so we need to type cast the return value to a *JButton*. We then retrieve the index of that button's corresponding label by calling the *getIndexOfLabel* method with *model*, passing the text of the button. We then check if the user won or lost by calling the *isCorrect* method of the *ColorGridGame* interface with *model*, passing that index. Depending on the result, we pop up a dialog box telling the user if he or she has won or lost (lines 50–53). Disabling the buttons after this is left as an exercise.

Finally, the *PlayColorCount* class, shown in **Example 16.28**, includes the *main* method to create a color count application. We declare an array of three *Colors* at line 12, declare a parallel array of *Strings* at line 13, create the *ColorFrequencyGame* object *game* at lines 14–15 with them, and create a *BorderedLabelGridView* object *gameGui* at lines 16–17. Using *game* and *gameGui*, we create a *ColorGridGameController* at lines 20–21. Note that *game* “is a” *ColorGridGame* object because *ColorFrequencyGame* inherits from *ColorGridGame*. **Figure 16.28** shows a run of this example, after the user has clicked on the button “BLUE.” To play the game with more colors, we could simply add colors and labels to the *colors* and *labels* array.

Example 16.28 The *PlayColorCount* Class

```java
/** PlayColorCount class
*   Anderson, Franceschi
*/

import javax.swing.JFrame;
import java.awt.Color;

public class PlayColorCount
{
 public static void main( String [ ] args )
 {
  Color [ ] colors = { Color.RED, Color.GREEN, Color.BLUE };
  String [ ] labels = { "RED", "GREEN", "BLUE" };
  ColorFrequencyGame game
    = new ColorFrequencyGame( 8, colors, labels );
  BorderedLabelGridView gameGui
    = new BorderedLabelGridView( colors.length, game.getSize( ) );
  gameGui.setSize( 380, 300 );
  gameGui.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
  ColorGridGameController controller
    = new ColorGridGameController( game, gameGui );
 }
}
```

16.15 Programming Activity 2: Working with Layout Managers

In this Programming Activity, you will complete the implementation of a version of the Tile Puzzle game using a more complex GUI. As it stands, the application compiles and runs, but is missing a lot of code. **Figure 16.29** shows the window that will open when you run the application without adding your code.

Figure 16.29 The Starting Window When Running the Prewritten Code

Description

Once you have completed the five tasks of this Programming Activity, you should see the window in **Figure 16.30** when you run your program and click on the “3-by-3” button.

Figure 16.30 The Starting Window When the Activity Is Completed

Description

When you click on one of the buttons labeled “3-by-3”, “4-by-4”, or “5-by-5”, the tile puzzle will reset to a grid of that size.

In addition to the *TilePuzzle* class, we provide you with a prewritten *Game* class, which encapsulates a Tile Puzzle game in a panel. We have implemented the *Game* class as a *JPanel* component, so you can add it to your window as you would any other panel. It has two important methods, shown in **Table 16.26**. Thus, your job in this Programming Activity is not to write the game code, but to organize components in a window.

The *Game* Class API

Game **Class API**	
Constructor	
Class	**Constructor**
`Game`	`Game( int nSides )`
instantiates a tile puzzle as an *nSides*-by-*nSides* grid	
Method	
Return value	**Method name and argument list**
`void`	`setUpGame( int nSides )`
resets the grid as an *nSides*-by-*nSides* grid	

Description

Your job is to:

1. Declare a *JPanel top* and three *JButtons* that will be added to the “north” part of the window.
2. Set the layout managers for the *game* panel and the top panel.

3. Add the *top* and the *game* panels.
4. Code an appropriate *private* listener class.
5. Instantiate the listener and register it on the appropriate components.

Instructions

Copy the source files in the Programming Activity 2 folder for this chapter to a folder on your computer.

1. Write the code to declare the needed instance variables. Load the *NestedLayoutPractice.java* source file and search for five asterisks in a row (*****). This will position you to the instance variables declaration.

```
// ***** Task 1: declare a JPanel named top
// also declare three JButton instance variables
// that will be added to the JPanel top
// these buttons will determine the grid size of the game:
//  3-by-3, 4-by-4, or 5-by-5

// task 1 ends here
```

Description

1. Next, write the code to set the layout manager of the window and add the component *game* in the center of the window. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you inside the constructor.

```
 // ***** Task 2: student code starts here
 // instantiate the BorderLayout manager bl
// set the layout manager of the content pane contents to bl

game = new Game( 3 );  // instantiating the Game object
// add game to the center of the content pane

// task 2 ends here
```

Description

1. Next, write the code to instantiate the *JPanel* top component, set its layout, instantiate the buttons from task 1, add them to *top*, and finally add *top* as the north component for our overall window. In the *NestedLayoutPractice .java* source file, search again for five asterisks in a row (*****). This will position you inside the constructor.

```
// ***** Task 3: Student code restarts here

// instantiate the JPanel component named top

// set the layout of top to a 1-by-3 grid

// instantiate the JButtons that determine the grid size

// add the buttons to JPanel top

// add JPanel top to the content pane as its north component

 // task 3 ends here
```

Description

1. Next, write the code for the *private* inner class that implements the appropriate listener. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you between the constructor and the *main* method.

```
// ***** Task 4: Student code restarts here
// create a private inner class that implements ActionListener
// your method should identify which of the 3 buttons was the
//   source of the event.
// depending on which button was pressed,
//   call the setUpGame method of the Game class
//   with arguments 3, 4, or 5
// the API of that method is:
//   public void setUpGame( int nSides )
// task 4 ends here
```

Description

1. Next, write the code to declare and instantiate a listener, and register it on the appropriate components. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you inside the constructor.

```
// ***** Task 5: Student code restarts here
// Note: search for and complete Task 4 before performing this task
// declare and instantiate an ActionListener
// register the listener on the 3 buttons
//   that you declared in Task 1

 // task 5 ends here
```

Description

After completing each task, compile your code.

When you have finished writing all the code, compile the source code and run the *NestedLayoutPractice* application. Try clicking on the three buttons that you added.

DISCUSSION QUESTIONS

1. Identify the various layout managers you used and the panels they manage.
2. Explain why the east and west areas do not show up on the window.

CHAPTER REVIEW

16.16 Chapter Summary

- A graphical user interface allows the user to interact with an application through mouse clicks, mouse movements, the keyboard, and visual input components.
- The *JFrame* class provides the capabilities for creating a window that will hold GUI components.
- A constructor in a GUI application should call the constructor of the *JFrame* superclass, get an object reference to the content pane, set the layout manager, instantiate each component and add it to the window, set the size of the window, and make the window visible.
- A component is an object that has a graphical representation and that displays information, collects data from the user, or allows the user to initiate program functions.
- Java provides a set of GUI components in the *javax.swing* package.
- A *JLabel* component can display text or an image.
- The *FlowLayout* layout manager arranges components in rows from left to right, starting a new row whenever a newly added component does not fit into the current row. If the window is resized, the components are rearranged.
- Event-driven programming consists of setting up interactive

components and event handlers and responding to events generated by user interaction with the components.

- Use the **Model-View-Controller** architecture to make applications as reusable as possible. The **Model** encapsulates the application's functionality; the **View** encapsulates the user interface of the application; and the **Controller** is the middleman between the View and the Model.
- To allow a user to interact with a component, we need to instantiate an object of that class, write an event handler class (called a listener), instantiate an object of the event handler class, and register that listener on the component.
- Event handlers implement a listener interface in the *java.awt.event* or the *javax.swing.event* package. The listener methods receive as a parameter an event object, which encapsulates information about the user interaction. The *getSource* method can be called to determine which component fired the event.
- Event handlers usually are instantiated as *private* inner classes so the handler will have access to the components of the application.
- A *JTextField* component displays a text field for user input. A *JPasswordField* component accepts user input without echoing the characters typed. A *JTextArea* component displays a multiple-line text input area. Events fired by the *JTextField* and *JPasswordField* components generate an *ActionEvent* object and require an *ActionListener* to handle the event.
- A *JButton* component implements a command button used for initiating operations. Clicking on a *JButton* component generates an *ActionEvent* object and requires an *ActionListener* to handle the event.
- *JRadioButton* components allow the user to select one of several mutually exclusive options. Clicking on any radio button deselects any previously selected option. *JRadioButton* components need to be added to a *ButtonGroup*, which manages the mutual exclusivity of the buttons. *JCheckBox* components are toggle buttons;

successive clicks on a *JCheckBox* component alternately select and deselect that option. Events fired by these components generate an *ItemEvent* object and use an *ItemListener* to handle the event.

- A *JComboBox* implements a drop-down list. The user can select only one item from the list. A *JComboBox* fires an *ItemEvent*, so the event handler must implement the *ItemListener* interface.
- Adapter classes, which *implement* an interface and provide empty bodies for each method, are useful when only one of multiple component actions is processed.
- *MouseAdapter* and *MouseMotionAdapter* are adapter classes for the *MouseListener* and *MouseMotionListener* interfaces, respectively.
- The *GridLayout* layout manager arranges components into equally sized cells in rows and columns.
- A *BorderLayout* layout manager, which is the default layout manager for the *JFrame* class, organizes a container into five areas: north, south, west, east, and center, with each area holding at most one component. The size of each area expands or contracts depending on the size of the component in that area, the sizes of the components in the other areas, and whether the other areas contain a component.
- A *JPanel* component can be used as a general-purpose container. To create a complex arrangement of GUI components, we place several components into a panel and place the panel into the content pane of the current *JFrame*. Each panel and the content pane has its own layout manager.

16.17 Exercises, Problems, and Projects

16.17.1 Multiple Choice Exercises

1. An example of a GUI component class is

    - *ActionEvent*.
    - *actionPerformed*.
    - *JTextField*.
    - *ActionListener*.

6. What are the primary uses of GUI components? (Check all that apply.)

    - to display information
    - to facilitate the coding of methods
    - to let the user control the program
    - to collect information from the user

11. In what package do you find the *JButton*, *JTextField*, and *JComboBox* classes?

    - *javax.swing*
    - *java.swing*
    - *javax.awt*
    - *java.awt*
    - *java.io*

17. Components can be hidden.

    - true
    - false

20. In order to process an event when the user clicks on a button, what should the programmer do? (Check all that apply.)

    - Code a class that implements the *ActionListener* interface.
    - Declare and instantiate an object reference (a listener) of the class above.
    - Call the *actionPerformed* method.
    - Register the listener on the button.

25. Assuming everything has been coded correctly, what happens when the user clicks a button?

    - The *actionPerformed* method executes.
    - The *JButton* constructor executes.
    - The *main* method executes.

29. If you visit Oracle's Java website (*www.oracle.com/technetwork/java*) and look at the *KeyListener* interface, you will find that it has three methods: *keyPressed*, *keyTyped*, and *keyReleased*. We want to build a class that implements *KeyListener*. Which of the three methods should we implement?

    - *keyPressed* only
    - *keyReleased* only
    - *keyTyped* only
    - All three methods

34. You are designing a GUI with three buttons; a different action will be taken depending on which button the user clicks. You want to code only one *private* class implementing the *ActionListener* interface. Inside the *actionPerformed* method, which method do you call to determine which button was clicked?

    - *getButton*
    - *getSource*
    - *getOrigin*

38. A class extending the *JFrame* class can also implement a listener interface.

    - true
    - false

41. *NewLayout* is a layout manager.

    - true

- false

44. In the following code:

```
GridLayout gl = new GridLayout( 6, 4 );
```

Description
what do the arguments 6 and 4 specify?

- 6 refers to the number of columns and 4 to the number of rows.
- 4 refers to the number of columns and 6 to the number of rows.
- There will be 6 components organized in 4 different areas.
- There will be 4 components organized in 6 different areas.

49. What is the maximum number of components that a *BorderLayout* can manage?

- 2
- 3
- 4
- 5
- 6

55. In the following code:

```
BorderLayout bl = new BorderLayout( 7, 3 );
```

Description
what do the arguments 7 and 3 represent?

- the horizontal and vertical gaps between the five areas of the component
- the vertical and horizontal gaps between the five areas of the component
- the number of rows and columns in the component
- the number of columns and rows in the component

60. In the following code:

    ```
    contents.add( button, BorderLayout.NORTH );
    ```

    Description
    what is the data type of the second argument?

    - *int*
    - *String*
    - *BorderLayout*
    - *NORTH*

65. Components can be nested.

    - true
    - false

16.17.2 Reading and Understanding Code

For Questions 16 to 21, consider the following code:

```
import javax.swing.*;
import java.awt.*;
import java.awt.event.*;
public class Game extends JFrame
{
 private JButton b1, b2, b3, b4;
 private Container contents;
 public Game( )
 {
  super( "Play this game" );
  contents = getContentPane( );
  contents.setLayout( new GridLayout( 2, 2 ) );
  b1 = new JButton( "Button 1" );
  b2 = new JButton( "Button 2" );
  b3 = new JButton( "Button 3" );
  b4 = new JButton( "Button 4" );
  contents.add( b1 );
  contents.add( b2 );
  contents.add( b3 );

  MyHandler mh = new MyHandler( );
  b1.addActionListener( mh );
  b2.addActionListener( mh );

  setSize( 400, 400 );
  setVisible( true );
 }

 private class MyHandler implements ActionListener
 {
  public void actionPerformed( ActionEvent ae )
  {
   System.out.println( "Hello" );
   if ( ae.getSource( ) == b2 )
      System.out.println( "Hello again" );
  }
 }
 public static void main( String [ ] args )
 {
  Game g = new Game( );
  g.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

1. How many buttons will be displayed in the window?
2. How are the buttons organized in the window?
3. What is the text in the title bar of the window?
4. What happens when the user clicks on the button that says “Button 1”?
5. What happens when the user clicks on the button that says “Button 2”?
6. What happens when the user clicks on the button that says “Button 3”?

For Questions 22 to 26, consider the following code:

```
 import javax.swing.*;
 import java.awt.*;
 import java.awt.event.*;

 public class Game extends JFrame
 {
  private JCheckBox c1, c2, c3;
 private int value1, value2, value3;
 private Container contents;
 public Game( )
 {
  super( "Play this game" );
  contents = getContentPane( );
  contents.setLayout( new FlowLayout( ) );
  c1 = new JCheckBox( "Choice 1" );
  c2 = new JCheckBox( "Choice 2" );
  c3 = new JCheckBox( "Choice 3" );
  contents.add( c1 );
  contents.add( c2 );
  contents.add( c3 );
  MyHandler mh = new MyHandler( );
  c1.addItemListener( mh );
  c2.addItemListener( mh );
  c3.addItemListener( mh );

  setSize( 400, 400 );
  setVisible( true );
 }

 private class MyHandler implements ItemListener
 {
  public void itemStateChanged( ItemEvent ie )
  {
    if ( ie.getSource( ) == c1 )
    {
      if ( ie.getStateChange( ) == ItemEvent.SELECTED )
        value1 = 1;
      else
        value1 = 0;
    }
    else if ( ie.getSource( ) == c2 )
    {
     if ( ie.getStateChange( ) == ItemEvent.SELECTED )
       value2 = 2;
     else
       value2 = 0;
    }
    else if ( ie.getSource( ) == c3 )
    {
      if ( ie.getStateChange( ) == ItemEvent.SELECTED )
        value3 = 4;
      else
        value3 = 0;
   }
   System.out.println( ( value1 + value2 + value3 ) );
  }
 }
 public static void main( String [ ] args )
 {
   Game g = new Game( );
   g.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

1. How many checkboxes will be displayed in the window?
2. How are the checkboxes organized in the window?
3. What happens when the user checks “Choice 3” only?
4. What happens when the user checks “Choice 1”, then checks “Choice 3”?
5. What happens when the user checks “Choice 1”, then “Choice 2”, then “Choice 3”?

16.17.3 Fill In the Code

For Questions 27 to 32, consider the following class:

```
import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class A extends JFrame
{
 private Container c;
 private JButton b;
 private JTextField tf;

}
```

Description

1. Inside the constructor, this code assigns the content pane of the frame to the *Container c*:

```
  // your code goes here
```

Description

2. Inside the constructor, this code instantiates the button *b* with the text “Button”:

```
// your code goes here
```

Description

3. Inside the constructor, this code instantiates the text field *tf*; after instantiation, the text field should be empty, but have space for 10 characters:

```
// your code goes here
```

Description

4. Inside the constructor, and assuming that *c* has been assigned the content pane, this code sets the layout manager of the content pane to a 2-by-1 grid layout manager:

```
// your code goes here
```

Description

5. Inside the *actionPerformed* method of a *private* inner class implementing the *ActionListener* interface, this code changes the text of *tf* to “Button clicked” if the button *b* was clicked; otherwise, nothing happens:

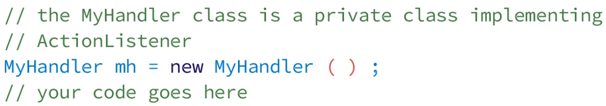
```
public void actionPerformed ( ActionEvent ae )
{
// your code goes here

}
```

Description

6. Inside the constructor, this code registers the listener *mh*

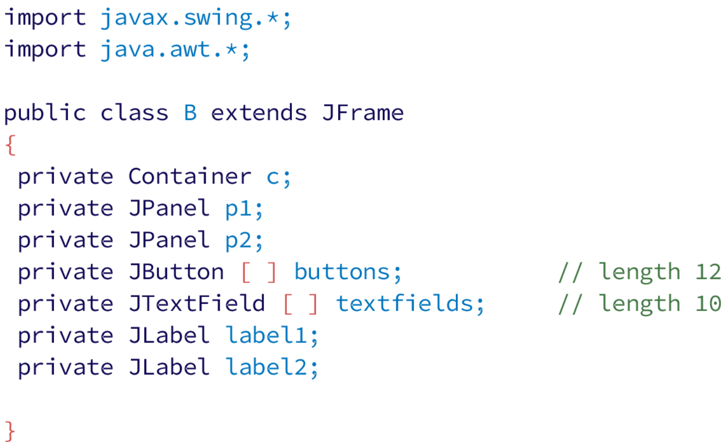
on the button *b*:



```
// the MyHandler class is a private class implementing
// ActionListener
MyHandler mh = new MyHandler ( ) ;
// your code goes here
```

Description

For Questions 33 to 41, consider the following class:



```
import javax.swing.*;
import java.awt.*;

public class B extends JFrame
{
 private Container c;
 private JPanel p1;
 private JPanel p2;
 private JButton [ ] buttons;          // length 12
 private JTextField [ ] textfields;    // length 10
 private JLabel label1;
 private JLabel label2;

}
```

Description

Also, assume that all the instance variables have been instantiated and you are coding inside the constructor.

1. This code sets the layout manager of the content pane to be a border layout manager.

```
// your code goes here
```

Description

2. This code adds *label1* to the north area of the window.

```
// your code goes here
```

Description

3. This code adds *label2* to the east area of the window.

```
// your code goes here
```

   Description

4. This code sets the layout manager of the panel *p1* to be a 3-by-4 grid layout manager.

```
// your code goes here
```

   Description

5. This code places all the buttons of the array buttons inside the panel *p1*.

```
// your code goes here
```

   Description

6. This code adds the panel *p1* in the center area of the window.

```
// your code goes here
```

   Description

7. This code sets the layout manager of the panel *p2* to a 5-by-2 grid with four pixels between cells, both horizontally and vertically.

```
// your code goes here
```

   Description

8. This code places all the text fields of the array *textfields* inside the panel *p2*.

```
// your code goes here
```

Description

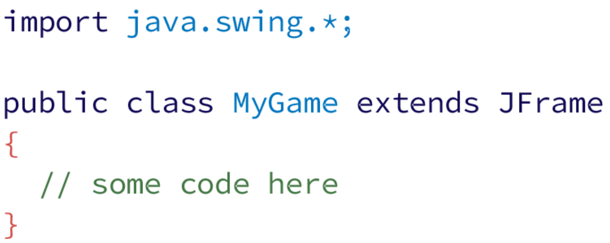
9. This code adds the panel *p2* in the west area of the window.

```
// your code goes here
```

Description

16.17.4 Identifying Errors in Code

1. Where is the error in this code sequence?

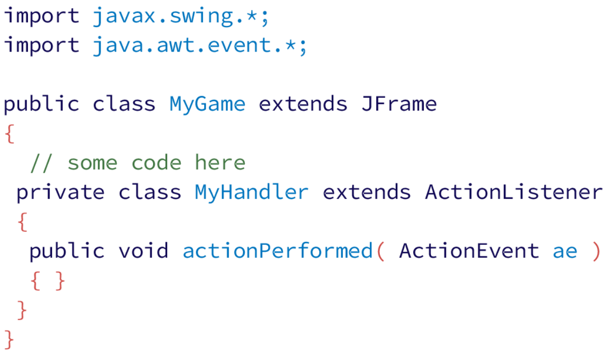


```
import java.swing.*;

public class MyGame extends JFrame
{
   // some code here
}
```

Description

2. Where is the error in this code sequence?



```
import javax.swing.*;
import java.awt.event.*;

public class MyGame extends JFrame
{
   // some code here
 private class MyHandler extends ActionListener
 {
  public void actionPerformed( ActionEvent ae )
  { }
 }
}
```

Description

3. Where is the error in this code sequence?

```
import javax.swing.*;
import java.awt.event.*;

public class MyGame extends JFrame
{
 // some code here
 private class MyHandler implements ItemListener
 {
  public void actionPerformed( ActionEvent ae )
  { }
 }
}
```

Description

4. Where is the error in this code sequence?

```
import javax.swing.*;
import java.awt.event.*;

public class MyGame extends JFrame
{
 // some code here
 private class MyHandler implements ItemListener
 {
  public void itemStateChanged( ActionEvent e )
  { }
 }
}
```

Description

16.17.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. You coded the following in the file *MyGame.java*:

```
import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class MyGame extends JFrame
{
 private Container c;
 private JLabel l;

 public MyGame( )
 {
  super( "My Game" );
  c = getContentPane( );
  c.setLayout( new FlowLayout( ) );
  c.add( l );  // Line 15
 }

 public static void main( String [ ] args )
 {
  MyGame mg = new MyGame( ); // Line 20
 }
}
```

Description

The code compiles, but at run time, you get the following output:

```
Exception in thread "main" java.lang.NullPointerException:
Cannot read field "parent" because "comp" is null
           at java.awt.Container.addImpl(Container.Java:1121)
           at java.awt.Container.add(Container.Java:440)
           at MyGame.<init>(MyGame.java:15)
           at MyGame.main(MyGame.java:20)
```

Description

Explain what the problem is and how to fix it.

2. You coded the following in the file *MyGame.java*:

```
import javax.swing.*;

public class MyGame extends JFrame
{
    public MyGame( )
    {
     super( "My Game" );
     setSize( 400, 400 );
    }
    public static void main( String [ ] args )
    {
     MyGame mg = new MyGame( );
    }
}
```

Description

The code compiles, but at run time, you cannot see the window and the code terminates.

Explain what the problem is and how to fix it.

3. You coded the following in the file *MyGame.java*:

```
import javax.swing.*;
import java.awt.*;

public class MyGame extends JFrame
{
 private Container c;
 private JTextField tf;

 public MyGame( )
 {
  super( "My Game" );
  c = getContentPane( );
  tf = new JTextField( "Hello" );
  c.add( tf, NORTH );
  setSize( 400, 400 );
  setVisible( true );
 }
 public static void main( String [ ] args )
 {
  MyGame mg = new MyGame( );
 }
}
```

Description

When you compile your code, you get the following error:

```
MyGame.java:14: error: cannot find symbol
     c.add( tf, NORTH );
                ^
   symbol:   variable NORTH
   location: class MyGame
1 error
```

Description

Explain what the problem is and how to fix it.

4. You coded the following in the file *MyGame.java*:

```
import javax.swing.*;
import java.awt.*;

public class MyGame extends JFrame
{
    // Some code here
    private class MyHandler implements ActionListener
    {
     public void actionPerformed( ActionEvent ae )
     { }
    }
}
```

Description

When you compile your code, you get the following error:

```
MyGame.java:7: error: cannot find symbol
     private class MyHandler implements ActionListener
                                       ^
   symbol: class ActionListener
   location: class MyGame
MyGame.java:9: error: cannot find symbol
     public void actionPerformed( ActionEvent ae )

     symbol: class ActionEvent
     location: class MyGame.MyHandler
  2 errors
```

Description

Explain what the problem is and how to fix it.

5. You coded the following in the *MyGame.java* file:

```
import javax.swing.*;
import java.awt.*;
import java.awt.event.*;

public class MyGame extends JFrame
{
 private JButton b;
 private JTextField tf;
 private Container contents;
 public MyGame( )
 {
  super( "Play this game" );
  contents = getContentPane( );
  contents.setLayout( new GridLayout( 1, 2 ) );
  b = new JButton( "Click here" );
  tf = new JTextField( "Hello" );
  contents.add( b );
  contents.add( tf );
  setSize( 400, 400 );
  setVisible( true );
 }

 private class MyHandler implements ActionListener
 {
  public void actionPerformed( ActionEvent ae )
  {
   tf.setText( "Hi" );
  }
 }
 public static void main( String [ ] args )
 {
   MyGame g = new MyGame( );
   g.setDefaultCloseOperation( JFrame.EXIT_ON_CLOSE );
 }
}
```

Description

The code compiles and runs. However, when you click the button, the text in the text field does not change.

Explain what the problem is and how to fix it.

16.17.6 Write a Short Program

1. Write a program that displays a text field and two buttons labeled “uppercase” and “lowercase”. When the user clicks on the uppercase button, the text changes to uppercase; when the user clicks on the lowercase button, the text changes to lowercase.

2. Write a program with two radio buttons and a text field. When the user clicks on one radio button, the text changes to lowercase; when the user clicks on the other radio button, the text changes to uppercase.
3. Write a program with two checkboxes and a text field. When no checkbox is selected, no text shows in the text field. When only the first checkbox is selected, the word “hello” shows in lowercase. When only the second checkbox is selected, the word “HELLO” shows in uppercase. When both checkboxes are selected, the word “HeLlO” shows (lower- and uppercase letters alternate).
4. Write a program with three radio buttons and a circle. (You can choose whether you draw the circle or if the circle is a label image.) When the user clicks on the first radio button, the circle becomes red. When the user clicks on the second radio button, the circle turns orange. When the user clicks on the third radio button, the circle becomes blue.
5. Write a program with three checkboxes and a circle drawn in black. Like the checkbox example in the chapter, each checkbox represents a color (red, blue, or green). Depending on the checkboxes selected, compute the resulting color as follows. If a checkbox is selected, assign the value 255 to the amount of the corresponding color. If a checkbox is not selected, assign 0 to the amount of the corresponding color. For example, if the checkboxes representing the colors red and blue are selected, the resulting color should be *Color (255, 0, 255*). Color the circle appropriately.
6. Write a program that simulates a guessing game in a GUI program. Ask the user for a number between 1 and 6 in a text field, then roll a die randomly and tell the user if he or

she won. Write the program in such a way that any invalid user input (i.e., not an integer between 1 and 6) is rejected and the user is asked again for input.

7. Write a program that simulates a guessing game in a GUI program. Generate a random number between 1 and 100; that number is hidden from the user. Ask the user for a number between 1 and 100 in a text field, then tell the user whether the number is too high, too low, or the correct number. Let the user continue guessing until he or she guesses the correct number.
8. Modify the *JComboBox* example in this chapter to use *JList* instead.

9. Write a program that displays a 4-by-6 grid of buttons, each with some unique text. One button is the “winning” button, which your program determines randomly, inside the constructor. When the user clicks on a button, its text is changed to “No” if the button clicked is not the winning button, or to “Won” if the button clicked is the winning

button.

10. Same as Exercise 59 with the following additions: Keep track of how many times the user clicks on buttons. If the user has not won after five clicks, the text on the last button clicked should be changed to “Lost”. Once the user has lost or won, you should disable the game—that is, the buttons no longer respond to clicks from the user.
11. Write a program that displays in the title of the window the position of the mouse as the user moves the mouse around the window.
12. Write a program that draws a small circle that follows the mouse as the user moves the mouse around the window.

16.17.7 Programming Projects

1. Write a GUI-based tic-tac-toe game for two players.
2. Write a GUI-based program that analyzes a word. The user will type the word in a text field. Provide buttons for the following:

    - One button, when clicked, displays the length of the word.
    - Another button, when clicked, displays the number of vowels in the word.
    - Another button, when clicked, displays the number of uppercase letters in the word.

    For this, you should design and code a separate (non-GUI) class encapsulating a word and its analysis, then instantiate an object of that class inside your GUI class and call the various methods as needed.

6. Write a GUI-based program that analyzes a soccer game. The user will type the names of two teams and the score of the game in four text fields. You should add appropriate

labels and create buttons for the following:

- One button, when clicked, displays which team won the game.
- Another button, when clicked, displays the game score.
- Another button, when clicked, displays by how many goals the winning team won.

For this, you should design and code a separate (non-GUI) class encapsulating a soccer game, then instantiate an object of that class inside your GUI class and call the various methods as needed.

10. Write a GUI-based program that analyzes a round of golf. You will retrieve the data for 18 holes from a text file. On each line in the file will be the par for that hole (3, 4, or 5) and your score for that hole. Your program should read the file and display a combo box listing the 18 holes. When the user selects a hole, the score for that hole should be displayed in a label. Provide buttons for the following:

    - One button, when clicked, displays whether your overall score was over par, under par, or par.
    - Another button, when clicked, displays the number of holes for which you made par.
    - Another button, when clicked, displays how many birdies you scored (a birdie on a hole is 1 under par).

    For this, you should design and code a separate (non-GUI) class encapsulating the analysis, then instantiate an object of that class inside your GUI class and call the various methods as needed.

14. Write a GUI-based program that analyzes statistics for tennis players. You will retrieve the data from a text file. On each line in the file will be the name of a player, the player’s number of wins for the year, and the player’s

number of losses for the year. Your program should read the file and display the list of players. When the user selects a player, the winning percentage of the player should be displayed in a label. Provide buttons for the scenarios that follow.

- One button, when clicked, displays which player had the most wins for the year.
- Another button, when clicked, displays which player had the highest winning percentage for the year.
- Another button, when clicked, displays how many players had a winning record for the year.

For this, you should design and code a separate (non-GUI) class encapsulating the tennis statistics analysis, then instantiate an object of that class inside your GUI class and call the various methods as needed.

18. Write a GUI-based program that simulates the selection of a basketball team. You will retrieve the data from a text file containing 10 lines. On each line will be the name of a player. Your program needs to read the file and display 10 checkboxes representing the 10 players. A text area will display the team, made up of the players being selected. A basketball team has five players. Your program should not allow the user to change his or her selection after the team has five players. Every time the user checks or unchecks a checkbox, the team in the text area should be updated accordingly. Provide buttons for the following:

    - One button, when clicked, displays how many players are currently on the team.
    - Another button, when clicked, displays how many players remain unselected.

    For this, you should design and code a separate (non-GUI) class encapsulating the player selection process, then instantiate an object of that class inside your GUI class and call the various methods as needed.

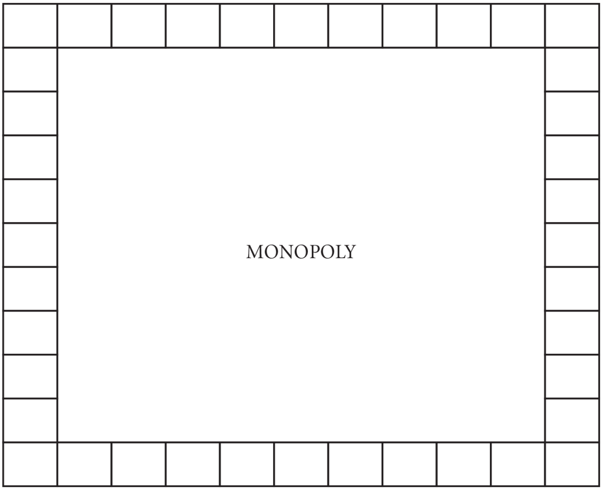
21. Write a GUI-based program that enables the user to choose a file containing an image. Your application then displays that image in a label. Your GUI should include a button and a label. When the user clicks on the button, open a file-choosing dialog box to enable the user to select a file (Hint: look up the *JFileChooser* class in the Java Class Library). The dialog box should show the files in the current directory with an extension of either *jpg* or *gif*.

22. Write a GUI-based program that displays a team on a soccer field. You will retrieve the data from a text file containing 11 lines. Each line will contain the name of a player. Your program should read the file and display the following window when it starts (you can assume that the players in the file are not in any particular order). Each cell is a button; when the user clicks on a button, the button replaces its text with the name of the player.

Left wing (11)	Striker (9)	Right wing (7)
Left midfielder (6)	Midfielder (10)	Right midfielder (8)
Left defender (3)	Stopper (4)	Right defender (2)
	Sweeper (5)	
	Goalie (1)	

---

1. Write a GUI-based program that displays a Monopoly® game. Add labels for the four train stations. Add buttons for all the Chance cells and set the text of these to a question mark. When the user clicks on one of the buttons, set its text to a message of your choice, chosen randomly from four messages.



Description

2. Write a GUI-based, simple drawing program. This program should have two buttons: one allowing the user to draw a rectangle, the other allowing the user to draw an oval. The user draws either a rectangle or an oval by pressing the mouse, dragging it, and releasing it. The top-left (*x*, *y*) coordinate of the rectangle (or enclosing rectangle for the oval) is where the user pressed the mouse button; the bottom-right point of the rectangle (or enclosing rectangle for the oval) drawn is where the user released the mouse

button.You will need to organize the window in two areas: one for the buttons, one for drawing.

16.17.8 Technical Writing

1. You are writing a program that you expect to be used by many users, with a different computer system. Would you use layout managers or would you hard code the position of components inside your GUI? Discuss.

16.17.9 Group Project (for a group of 1, 2, or 3 students)

1. Design and code a program that simulates an auction. You should consider the following:

   A file contains a list of items to be auctioned. You can decide on the format of this file and its contents. For example, the file could look like this:

   ```
   Oldsmobile, oldsmobile.gif, 100
   World Cup soccer ticket, soccerTickets.gif, 50
   Trip for 2 to Rome, trip.gif, 100
   ```

   In the preceding file sample, each line represents an item as follows: the first field is the item's description, the second field is the name of a file containing an image of the item, and the third field is the minimum bid. You can assume that each item's description is unique.

   Items are offered via an online-like auction. (You do not need to include any network programming; your program is a single-computer program.) Users of the program can choose which item to bid on from a list or a combo box. Along with displaying the description of the item, your program should show a picture of the item and the current highest bid (at the beginning, the current highest bid is the minimum bid). Users bid on an item by selecting the item, typing their name (you can assume that a different name will be used each time), and entering a price for the item. Your program should remember the highest bidder and the highest bid for each item by writing the information to a file.

Furthermore, each time a bid is made, the item’s highest bid, displayed on the screen, should be updated if necessary.

Chapter 17

Graphical User Interfaces Using JavaFX

CHAPTER CONTENTS

Introduction
17.1 The Structure of a JavaFX Application
17.2 GUI Controls
17.3 A Simple Control: *Label*
17.4 Event Handling: Managing User Interactions
17.5 Text Fields and Command Buttons
17.6 Radio Buttons and Checkboxes
17.7 **Programming Activity 1: Working with Buttons**
17.8 Combo Boxes
17.9 Sliders
17.10 Building a GUI Programmatically
17.11 Layout Containers: Dynamically Setting Up the GUI Using *GridPane*
17.12 *BorderPane* Layout, Animations, Sounds, and Lambda Expressions
17.13 Nesting Components
17.14 Mouse and Touch Events
17.15 Using a List to Display a Pie Chart

17.16 Using a List to Display a Dynamic Bar Chart
17.17 Using a Style Sheet to Style the View
17.18 **Programming Activity 2: Working with Layout Containers**
17.19 Chapter Summary
17.20 Exercises, Problems, and Projects

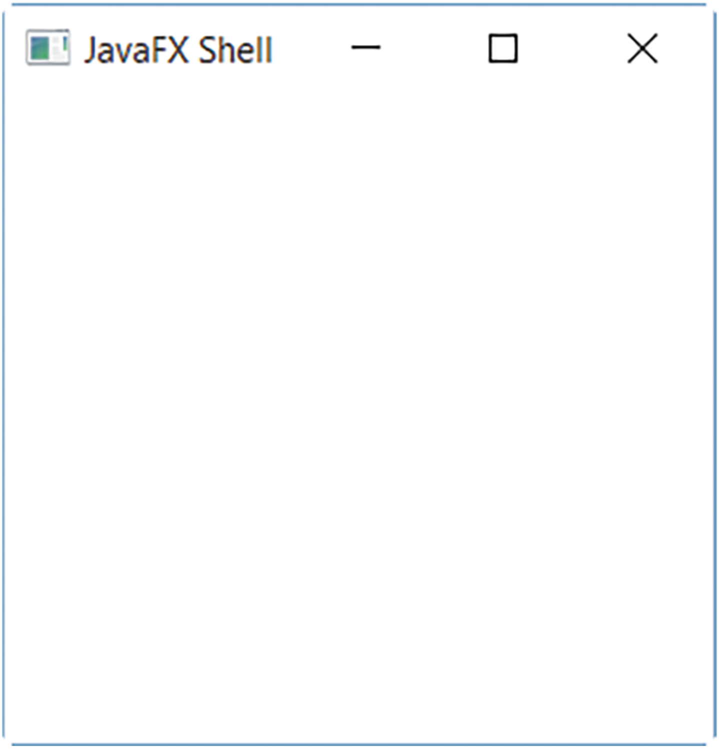
- 17.20.1 Multiple Choice Exercises
- 17.20.2 Reading and Understanding Code
- 17.20.3 Fill In the Code
- 17.20.4 Identifying Errors in Code
- 17.20.5 Debugging Area—Using Messages from the Java Compiler and Java JVM
- 17.20.6 Write a Short Program
- 17.20.7 Programming Projects
- 17.20.8 Technical Writing
- 17.20.9 Group Project

Introduction

Many applications we use every day have a Graphical User Interface, or GUI (pronounced Goo-ey). These GUIs allow the user to communicate to the application by entering text into boxes; pressing buttons; or selecting items from a list, a set of radio buttons, or checkboxes.

GUIs allow the user to drive the application by selecting the next function to be performed, entering the needed data, or setting program preferences, such as colors or fonts. Applications with GUIs are usually easier to learn and use because the interface is familiar to the user.

One way to create a GUI is to use the Swing components. Recently, Oracle introduced JavaFX, a new approach to making GUIs. All the classes needed to create a JavaFX application are automatically included with Java SE; nothing more needs to be downloaded. In this chapter, we present some of the many JavaFX classes, along with the main concepts associated with developing a JavaFX application.



17.1 The Structure of a JavaFX Application

The top-level structure in a JavaFX application is the **stage**, which corresponds to a window. A stage can have one or more **scenes**, which are top-level containers for **nodes** that make up the window contents. A node can be a user interface control, such as a button or a drop-down list; a layout; an image or other media; a graphical shape; a web browser; a chart; or a group. In this chapter, we concentrate on user interface controls, layouts, charts, and images.

To create a JavaFX GUI, we add nodes to a scene. These nodes are arranged in a hierarchy, called a **scene graph**, in which some nodes are children of other nodes. The top node is called the **root**.

JavaFX applications can be built in several ways. If we know which controls our interface needs and how they should be arranged, we can use **FXML**, a scripting language based on **XML** (**Extensible Markup Language)**. In this case, we create an FXML file where we specify the layout container and nodes and their properties. For dynamic GUIs where the number or types of controls are determined at runtime, we can define the number, type, properties, and positioning of controls programmatically (that is, through Java code).

In this chapter, we start by using FXML and use Java code later. By defining our GUI using FXML, we separate the GUI from the logic of the code. Also, FXML allows nonprogrammers to contribute to a team by defining the GUI without knowledge of programming.

REFERENCE POINT

You can get more information about the JavaFX classes at Oracle's Java website: *www.oracle.com/technetwork/java.*

Examples 17.1 and 17.2 show the basic structure of a JavaFX application that uses FXML.

Example 17.1 A JavaFX Shell Application

```java
/*  JavaFX Shell Application
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.HBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class FXShellApplication extends Application
{
  @Override
  // start is main entry point for the application.
  // It receives a Stage object - the main window for the
  // GUI application
  public void start( Stage stage ) // throws Exception
  {
    try
    {
      // Locate the FXML resource
      URL url
         = getClass( ).getResource( "fxml_shell.fxml" );

      // Load the FXML resource, instantiate root Node;
      // use appropriate layout class for root Node;
      // here we use HBox
      HBox root = FXMLLoader.load( url );

      // create a scene associated with the root
      // and set its width and height
      Scene scene = new Scene( root, 300, 275 );

      // assign the scene to the stage object
      stage.setScene( scene );

      // set title of stage (optional)
      stage.setTitle( "JavaFX Shell" );

      // make the stage visible
      stage.show( );
    }
    // The FXMLLoader load method throws an exception if
    // the FXML file is invalid or the URL was not found
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

Lines 5 through 10 import the classes we need in most applications. Notice that the JavaFX classes are stored in packages having the prefix of *javafx*.

At line 12, we define our class as inheriting from the *abstract Application* class, which is the entry point for all JavaFX applications. When a JavaFX application is launched, the runtime first calls the *init* method, and then *start*. When the application closes its last window or if it calls the *Platform.exit* method, the runtime calls the *stop* method. The *Application* class provides concrete implementations of the *init* and *stop* methods, so overriding *init* and *stop* is optional. The *Application* class defines the *start* method as *abstract*, however, so we must override the *start* method. **Table 17.1** shows some methods of the *Application* class.

Some Methods of the *Application* Class

<table>
<tr><th>Package</th><th>javafx.application</th></tr>
<tr><th>Return value</th><th>Method name and argument list</th></tr>
<tr><td><code>void</code></td><td><code>init( )</code></td></tr>
<tr><td colspan="2">called by the JavaFX runtime when the application is launched. Overriding this method is optional.</td></tr>
<tr><td><code>void</code></td><td><code>launch(String … args)</code></td></tr>
<tr><td colspan="2"><i>static</i> method that launches the application. Passes any command-line arguments to the application.</td></tr>
<tr><td><code>Application.Parameters</code></td><td><code>getParameters( )</code></td></tr>
<tr><td colspan="2">returns any command-line arguments as an <i>Application.Parameters</i> object.</td></tr>
<tr><td><code>void</code></td><td><code>start(Stage primaryStage)</code></td></tr>
<tr><td colspan="2">the main entry point for JavaFX applications. The application places its scene onto the <i>primaryStage</i>. This <i>abstract</i> method needs to be implemented.</td></tr>
<tr><td><code>void</code></td><td><code>stop( )</code></td></tr>
<tr><td colspan="2">called when the application signals that it is ready to end. Overriding this method is optional.</td></tr>
</table>

Description

SOFTWARE ENGINEERING TIP

Using the *@Override* annotation whenever you intend to override an inherited method reduces errors because the compiler alerts you if your method header is not correct.

Lines 14 through 50 define the *start* method. In line 14, we use the *@Override* annotation. It is good practice to use this annotation whenever we intend to override an inherited method. Using the annotation causes the compiler to alert us if our method header does not correctly override the method in the superclass.

A lot is happening in lines 22 through 29. The FXML file contains the definitions for our GUI components. In order to associate the FXML file with the application, we need to create a URL object containing the file's location; then we load the file as an application resource. We inherit the *getClass* method from the *Object* class. It returns the *Class* object associated with our application. We then use that object reference to call the *getResource* method in the *Class* class, shown in **Table 17.2**.

The *getResource* Method of the *Class<T>* Class

Package	**java.lang**
Return value	**Method name and argument list**
`URL`	`getResource( String resource )`
returns a URL object representing the location of the *resource,* or *null* if the *resource* is not found	

Description

Once we have a URL for the FXML file, we call the *static load* method of the *FXMLLoader* class, shown in **Table 17.3**, to instantiate the layout and components that we defined in our

FXML file. This method throws an *IOException* if the format of the FXML file is invalid. In this example, the top-level node is an *HBox* layout object, which arranges its child nodes horizontally across the window. The root and its children make up the scene graph. The return value from the *load* method is a reference to the top-level, or root, node in the FXML file.

The *load* Method of the *FXMLLoader* Class

Package	**javafx.fxml**
Return value	**Method name and argument list**
`<T> T`	`load( URL location )`
static method that instantiates the nodes defined in the FXML file specified by *location* and returns a reference to the root node	

Description

After we have the resources loaded, we instantiate a *Scene* object (line 33), which is the container for our GUI content. **Table 17.4** shows a constructor of the *Scene* class. Some of the other *Scene* constructors do not require width and height parameters. With those constructors, the scene is sized to fit its contents. For this scene, we specify the layout node returned from the *load* method as the root, and we size the scene to be 300 pixels wide and 275 pixels high.

A Constructor of the *Scene* Class

Package	**javafx.scene**
`Scene( Parent root, double width, double height )`	
instantiates the *Scene* with a top-level node of *root* and sets the width and height to the pixel values specified	

Description

Now we are ready to set the stage, literally. Notice that the *start* method receives a *Stage* object as a parameter (line 18). This corresponds to the top-level window. At line 36, we allocate our newly created scene to the *stage* object. At line 39, we set the text to appear in the title bar, and at line 42, we make the window visible. **Table 17.5** shows some useful methods of the *Stage* class.

Useful Methods of the *Stage* Class

Package	**javafx.stage**
Return value	**Method name and argument list**
`void`	`setScene( Scene scene )`
specifies the scene to be hosted by the *Stage*.	
`void`	`setTitle( String title )`
sets the text to appear in the window title bar.	
`void`	`show( )`
makes the window visible. By default, windows are not visible.	

Description

We placed most of the code in the *start* method into a *try* block because several exceptions can occur. If the *getResource* method of the *Class* class does not find the FXML file, it returns *null.* This causes a *NullPointerException* when the *FXMLLoader* *load* method tries to access the file. The *load* method also throws an *IOException* if the FXML file format is invalid. To simplify the examples in this chapter, we use one *catch* block (lines 44–49) that specifies *Exception*, which is a superclass of both *IOException* and *NullPointerException*. In the *catch* block, we print the stack trace to help with debugging errors in our applications. It is good software engineering practice, however, in the final application to catch each exception separately and output a meaningful message to the user.

COMMON ERROR TRAP

Windows are hidden by default. Be sure to call the *show* method at the end of the *start* method. Otherwise, the window will not appear.

SOFTWARE ENGINEERING TIP

Catch each possible exception separately. If recovering from the exception is not possible, output a meaningful message to the user.

REFERENCE POINT

You can get more information about FXML at *http://docs.oracle.com/javafx/2/get_started/jfxpub-get_started.htm*. For more information about XML, visit *http://www.w3.org/XML.*

At lines 52 through 55, we include the *main* method. Its only job is to start the application by calling the *launch* method of the *Application* class, passing any parameters that have been sent to the application. An application may access these parameters using the *getParameters* method.

In **Example 17.2**, we show a shell FXML file. In this file, we use FXML to define the layouts and controls that make up the GUI.

Example 17.2 Shell FXML file: *fxml_shell.fxml*

```
1 <?xml version="1.0" encoding="UTF-8"?>
2
3 <!-- import classes -->
4 <?import javafx.scene.layout.HBox ?>
5
6 <!-- use appropriate layout manager -->
7 <HBox xmlns:fx="http://javafx.com/fxml" >
8    <!-- define GUI components here -->
9 </HBox>
```

Description

Line 1 is the header. Like other lines that do not specify XML elements, it begins with <? and ends with ?>. It defines the XML version as 1.0 and the encoding to be UTF-8, which is essentially Unicode, except that the first 128 characters are stored as 8 bits. Lines 3, 6, and 8 are comments, which use the same syntax as an HTML comment; that is, they begin with <!-- and end with -->. These comments can span more than one line.

COMMON ERROR TRAP

Be sure to include an *import* statement for any controls or layout containers referenced in the FXML file. Omitting an *import* statement will generate an exception when the FXML Loader loads the file.

At line 4 we import the *HBox* class because it is the root element defined in this sample file. Similarly, we need to import any classes referenced in the FXML file.

At line 7, we have chosen the *HBox* layout class as an example. In other applications, we put the appropriate top-level layout class here, which becomes the root node for our layout. Lines 7 through 9 illustrate the syntax of an **element**, which we use to define the components of the GUI.

Elements begin with a **start tag** with the element’s name enclosed in angle brackets (< >). Some elements, such as the *HBox* definition here, have **closing tags**, which are simply the element’s name preceded by a forward slash (/), also enclosed in angle brackets (line 9). Some tags, illustrated later in this chapter, have an empty closing tag and end with />.

Elements can have **attributes**, which further define the element or set properties of the element. Attribute definitions are inserted between the element’s name and its closing tag.

The syntax for a JavaFX attribute is

```
attributeName = "value"
```

Description

or

```
attributeName = 'value'
```

Description

COMMON ERROR TRAP

Be sure to enclose attribute values in single or double quotes. Omitting one or both quotes will generate an exception when the FXML Loader loads the file.

At line 7, we define an attribute for the root layout:

```
xmlns:fx="http://javafx.com/fxml"
```

Description

This attribute defines the **namespace** for FXML elements. A namespace prevents duplication of variable names, called *name collisions*, by defining a scope for variable names.

Figure 17.1 shows the window created when we run *FXShellApplication.java.* Note that the text in the title bar is "JavaFX Shell" as set in Example 17.1, line 39. The window is empty because we have not added any controls. We add some content to a window in the next section.

17.2 GUI Controls

JavaFX provides an extensive set of classes that can be used to add a GUI to our applications. A GUI control performs at least one of these functions:

- Displays information
- Collects data from the user

- Allows the user to initiate program functions

Table 17.6 lists some JavaFX classes that encapsulate GUI controls. All classes listed in Table 17.6 belong to the package *javafx.scene.control*.

Selected GUI Controls and Their JavaFX Classes

Package	**javafx.scene.control**
JavaFX Class	**Purpose**
Label	Displays an image or read-only text. Labels are often used to identify the contents of *TextFields.*
TextField	A single-line text box for accepting user input.
Button	Command button that the user clicks to signal that an operation should be performed.
RadioButton	Toggle button that the user clicks to select one option in a group.
CheckBox	Toggle button that the user clicks to select or deselect 0, 1, or more options in a group.
ComboBox	List of options from which the user selects one item.
Slider	Displays a set of continuous values along a horizontal or vertical line. The user can select a value by moving the knob, or thumb.

Description

Figure 17.2 shows the hierarchy of some JavaFX controls. Recall that because of the “is a” relationship in inheritance, a subclass object is also an object of each of its superclasses. Thus, all the controls are a *Node* (an element of the scene), a *Parent (*a *Node* that can have children controls), a *Region* (a resizable container that can be styled), and a *Control* (a GUI component). Along the hierarchy, each control has gained methods and properties from its superclasses.

Figure 17.2 The Hierarchy of Some JavaFX Controls

Description

In our applications, we place the controls into the scene by using layout containers, which organize the controls according to each layout's rules. Some of these layout containers are shown in **Table 17.7.** These classes are in the *javafx.scene.layout* package.

Commonly Used JavaFX Layout Classes

Package	**javafx.scene.layout**
Layout Container	**Lays out its children nodes . . .**
HBox	In a single horizontal row.
VBox	In a single vertical column.
BorderPane	With at most one child in its top, left, right, bottom, and center positions.
GridPane	In a grid of rows and columns. A child can span more than one row or column.
StackPane	In a front-to-back stack.

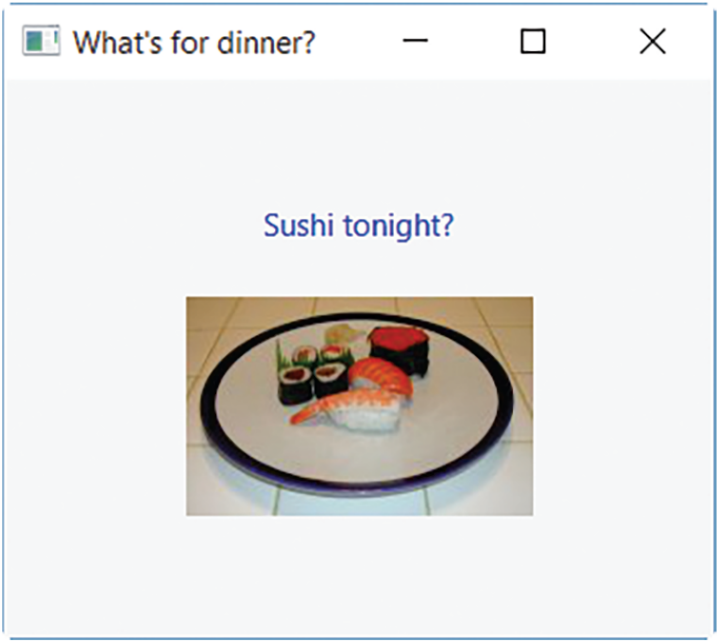
Description

The hierarchy of the layout classes is shown in **Figure 17.3**. Like the controls, the layout classes also inherit from *Node*, *Parent,* and *Region*. Instead of inheriting from *Control*, however, these classes inherit from *Pane,* which provides a method for accessing all the children in the scene graph. We use that method later in this chapter.

Figure 17.3 The Layout Classes Hierarchy

Description

In the examples in this chapter, we set the root node of our scenes to be one of these layouts and add controls, images, and even other layouts as child nodes. We show how to nest layouts in later examples in this chapter.



Sushi tonight?

17.3 A Simple Control: *Label*

Starting with our shell JavaFX application, let's add a simple control to the window, a *Label,* and an image, which we display through an *ImageView* node. **Example 17.3** shows the application code. Notice that the code is almost identical to Example 17.1, except for the name of the FXML file (line 22), the title bar text (line 32), and that the *root* node is a *VBox* layout (line 24).

Example 17.3 *Dinner.java*

```
/*  Displaying a Label and image
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.VBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class Dinner extends Application
{

  @Override
  public void start( Stage stage )
  {
    try
    {
      // find the XML resource
      URL url
         = getClass( ).getResource( "fxml_dinner.fxml" );
      // load the XML resource and instantiate the root node
      VBox root = FXMLLoader.load( url );

      // create a scene
      Scene scene = new Scene( root, 350, 275 );

      // set the scene
      stage.setScene( scene );
      // set title of stage
      stage.setTitle( "What's for dinner?" );
      // show the stage
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

Again, we have an accompanying FXML file, shown in **Example 17.4.** We begin this file like the shell FXML file, with the definition of the FXML version and encoding scheme (line 1);

then we import all the classes we reference (lines 3–5). In this file, we define the layout to be a *VBox* (lines 7–12). We use attributes to assign values to properties of the *VBox* layout (line 7); we set the *alignment* property to center the child nodes in the window and the *spacing* property to insert 25 pixels between the nodes in the layout.

Example 17.4 The *fxml_dinner.fxml* File

```
 1 <?xml version="1.0" encoding="UTF-8"?>
 2 
 3 <?import javafx.scene.control.*?>
 4 <?import javafx.scene.image.*?>
 5 <?import javafx.scene.layout.*?>
 6 
 7 <VBox id="root" alignment="CENTER" spacing="25" >
 8   <Label text="Sushi tonight?" textFill="BLUE" />
 9   <ImageView>
10      <Image url="@sushi.jpg" />
11   </ImageView>
12 </VBox>
```

Description

At line 8, we define a *Label* control and use attributes to set its text to “Sushi tonight?” and its text color (*textFill*) to blue. All attribute values must be plain text, enclosed in double quotes. If an object or primitive value is needed, the FXML Loader performs any necessary conversion. Thus for the text color, we specify the attribute value as “BLUE,” and the FXML Loader converts the text to the object *Color.BLUE*.

REFERENCE POINT

To find the properties that can be set for any layout or control, see the JavaFX class documentation. Remember also that controls inherit properties from their superclasses.

At lines 9 through 11, we define a second child node as an *ImageView* element. We set the *Image* property of the *ImageView* to the file “sushi.jpg” (line 10). We preface the filename with “@” to indicate that we are specifying the filename relative to the current folder. Thus, the file *sushi.jpg* is stored in the same folder as the *.java* file. When this application runs, we see the window shown in **Figure 17.4**.

17.4 Event Handling: Managing User Interactions

Now we know how to open a window in an application, and we know how to display a label and an image. The user, however, cannot yet interact with our application. We need to add some interesting GUI controls, such as text entry fields and a button. By interacting with those controls, the user can enter data and initiate operations in our programs.

GUI programming uses an **event-driven model**, as opposed to the procedural model of programming that we have used thus far. By event-driven, we mean that by using a GUI, we put the user in control of what happens next. For example, we might display some text entry fields, some buttons, and a selectable list of items. Then our program "sits back" and waits for the user to interact with the controls. When the user presses a button or selects an item from the list, our application responds by performing the operation the user requested. Then the application sits back again and waits for the user to press another button or select another item from the list. These user actions generate **events**. Thus, the processing of our application consists of responding to events caused by the user interacting with our GUI controls.

When the user interacts with a GUI control, the control **fires an event.** To handle that event, we register our application's interest in being notified when a particular event occurs, and we provide code—an **event handler**, also called a **listener**—to execute when the event occurs**.**

JavaFX supports and encourages the **Model-View-Controller** architecture for writing GUI applications. In this architecture,

- The **Model** manages the data of the application and its state.
- The **View** presents the user interface.
- The **Controller** handles events generated by the user and

communicates those changes to the Model, which updates its state accordingly and communicates any changes back to the Controller. The Controller then updates the View to reflect those changes.

These three components can be placed in the same or in different files.

17.5 Text Fields and Command Buttons

Let's illustrate event handling and the Model-View-Controller architecture with an example that allows a user to square or cube a number. We provide a *TextField* for entering the number; two *Button*s, one for squaring the number and the other for cubing the number; and *Labels* for displaying a prompt and for displaying the squared or cubed result.

The interface we want to create is shown in **Figure 17.5A**. **Figure 17.5B** shows the window after the user entered "3" into the *TextField* and clicked the "Cube" button.

Figure 17.5 (A) The Initial Window (B) The Window After User Interaction

Description

For this application, our Model, shown in **Example 17.5**, is minimal. It provides two *static* methods, *square* (lines 7–14) and *cube* (lines 16–23), to perform the calculations.

Example 17.5 The Model, *SimpleMath.java*

```
/*  Simple Math Class
    Anderson, Franceschi
*/

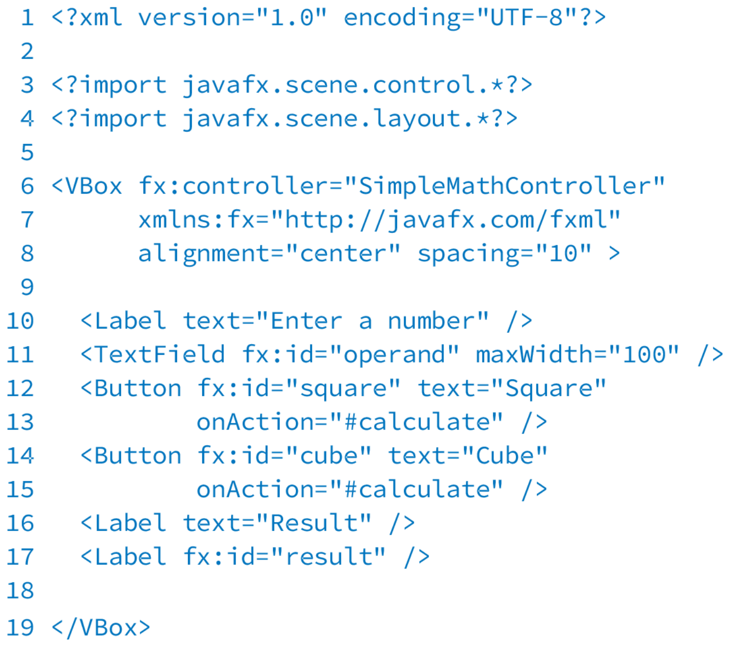
public class SimpleMath
{
  /** square method
  *  @param operand  number to square
  *  @return the square of operand
  */
  public static double square( double operand )
  {
    return operand * operand;
  }

  /** cube method
  *  @param operand  number to cube
  *  @return the cube of operand
  */
  public static double cube( double operand )
  {
    return operand * operand * operand;
  }
}
```

Description

The controls and their layout are defined in the FXML file, shown in **Example 17.6**, which acts as our View. Because we want to respond to the user clicking either button, we define a controller at line 6 using the *fx:controller* attribute of the layout container with its value set to the class name of the Java file that contains our controller. Thus, in this case, the controller is *SimpleMathController.java.*

Example 17.6 The View, *fxml_simple_math.fxml*



```
1 <?xml version="1.0" encoding="UTF-8"?>
2
3 <?import javafx.scene.control.*?>
4 <?import javafx.scene.layout.*?>
5
6 <VBox fx:controller="SimpleMathController"
7       xmlns:fx="http://javafx.com/fxml"
8       alignment="center" spacing="10" >
9
10   <Label text="Enter a number" />
11   <TextField fx:id="operand" maxWidth="100" />
12   <Button fx:id="square" text="Square"
13           onAction="#calculate" />
14   <Button fx:id="cube" text="Cube"
15           onAction="#calculate" />
16   <Label text="Result" />
17   <Label fx:id="result" />
18
19 </VBox>
```

Description

The two buttons are defined at lines 12 through 15. The *text* attribute specifies the wording to appear on the button. The *onAction* attribute specifies a method in the controller that should be executed when the user clicks the button. Thus, our controller must define a method named *calculate*. Usually, we code the method as accepting an *ActionEvent* object, as shown below, although this is not required.

```
void calculate( ActionEvent event )
```

Description

The *ActionEvent* object is automatically created when the user clicks a button, selects an item from a list or a menu, or presses the *Enter* key in a *TextField*. The *ActionEvent* object contains data we can query, such as which control fired the event.

The *calculate* method is our event handler or listener, and by setting the *onAction* attribute for a control, we **register** the event handler on our control: our buttons, in this example. Thus, when the user clicks on either of the buttons, the *calculate* method executes.

We have also used the *fx:id* attribute to define a name for all the controls that the controller needs to access. Assigning an *fx:id* to a control puts the control in the *fx* namespace, making the control accessible outside the file in which the control is defined. This allows the controller to access controls using their *fx:id* value.

Our controller is shown in **Example 17.7**. It defines as instance variables all the controls it needs to access using their *fx:id* names that we defined in the FXML file (lines 7–10). We use the *@FXML* annotation in front of the instance variable definitions to indicate that these controls, although defined as *private*, are also accessible to FXML.

Example 17.7 The Controller, *SimpleMathController.java*

```
 1 import javafx.event.ActionEvent;
 2 import javafx.fxml.FXML;
 3 import javafx.scene.control.*;
 4
 5 public class SimpleMathController
 6 {
 7   @FXML private TextField operand;
 8   @FXML private Label result;
 9   @FXML private Button square;
10   @FXML private Button cube;
11
12   @FXML protected void calculate( ActionEvent event )
13   {
14     try
15     {
16       double op = Double.parseDouble( operand.getText( ) );
17       if ( event.getSource( ) == square )
18         result.setText( String.valueOf( SimpleMath.square( op ) ) );
19       else if ( event.getSource( ) == cube )
20         result.setText( String.valueOf( SimpleMath.cube( op ) ) );
21     }
22     catch ( NumberFormatException nfe )
23     {
24       operand.setText( "" );
25       result.setText( "???" );
26     }
27   }
28 }
```

Description

The *calculate* method is defined at lines 12–27. We also precede the method header with the *@FXML* annotation, again to give FXML access to this *protected* method. The *calculate* method takes as a parameter an *ActionEvent* object. As mentioned, this object is created when the user clicks on the button and contains information about the event that occurred.

At line 16, we use the *getText* method to extract the text that the user typed into the *operand TextField.* The *getText* method is shown along with its companion *setText* method in **Table 17.8**. Because the *getText* method returns a *String,* we call the *static parseDouble* method of the *Double* wrapper class to convert the *String* to a *double*. We enclose this operation in a *try/catch* block (lines 14–26) because the *parseDouble* method throws a *NumberFormatException* if the text the user entered cannot be converted to a *double*.

Useful Methods of the *TextField* Class

Package	**javafx.scene.control**
Return value	**Method name and argument list**
`String`	`getText( )`
returns the text typed into the *TextField*	
`void`	`setText( String newText )`
sets the text in the *TextField* to *newText*	

Description

If the conversion goes well, we then determine which button the user pressed. The *ActionEvent* class provides a useful method, *getSource*, shown in **Table 17.9**, which we can use to determine which button the user actually clicked. At line 17, we test whether the user clicked the *square* button. If so, we call the *static square* method in our *SimpleMath* Model, passing the converted number and setting the *result Label* to the return value. Because the *setText* method requires a *String* argument, we call the *static valueOf* method of the *String* class to convert the return value to a *String*.

The *getSource* Method of the *ActionEvent* Class

Package	**javafx.event**
Return value	**Method name and argument list**
`Object`	`getSource( )`
returns the object on which the event was triggered	

Description

Similarly, at lines 19 and 20, we test whether the user clicked the *cube Button*; if so, we call the *static cube* method of the *SimpleMath* class and set the *result Label* to the return value.

Finally, *SimpleMathPractice*, the launch class, shown in **Example 17.8**, performs the usual operations of loading the *fxml_simple_math.fxml* file, setting the scene and stage parameters, and displaying the prepared window.

Example 17.8 *SimpleMathPractice.java*

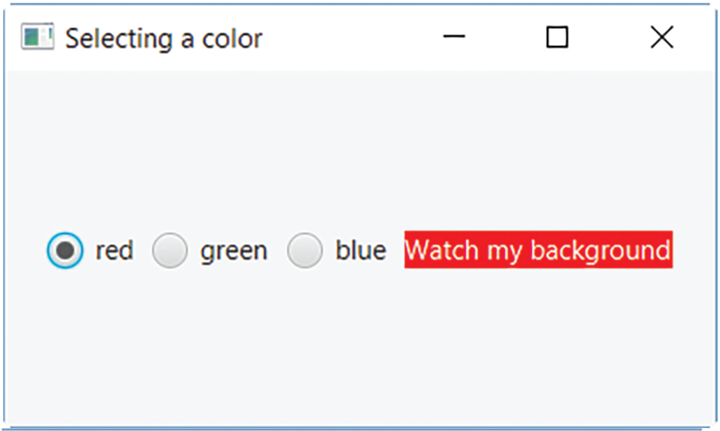
```java
/*  Simple Math Operations Using Buttons
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.VBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

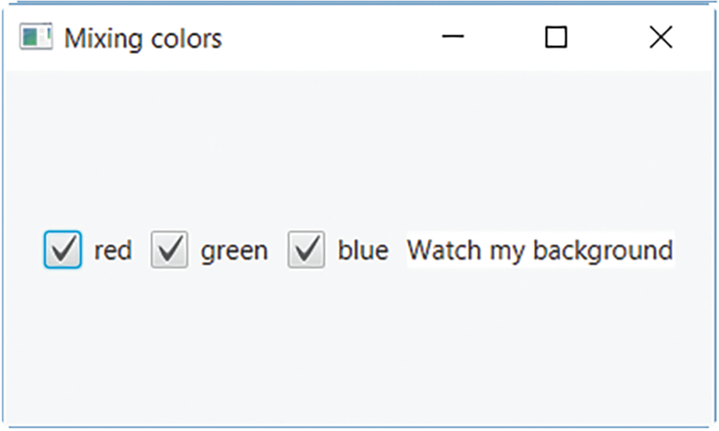
public class SimpleMathPractice extends Application
{
  @Override
  public void start( Stage stage ) // throws Exception
  {
    try
    {
      URL url =
         getClass( ).getResource( "fxml_simple_math.fxml" );
      VBox root = FXMLLoader.load( url );
      Scene scene = new Scene( root, 300, 275 );
      stage.setTitle( "Simple Math" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description



● red ○ green ○ blue Watch my background



☑ red ☑ green ☑ blue Watch my background

17.6 Radio Buttons and Checkboxes

If you have ever completed a survey on the web, you are probably familiar with radio buttons and checkboxes.

Radio buttons prompt the user to select one of several mutually exclusive options. Clicking on any radio button deselects any previously selected radio button. Thus, in a group of radio buttons, a user can select only one option at a time.

Checkboxes are often associated with the instruction “check all that apply”; that is, the user is asked to select 0, 1, or more options. A checkbox is a toggle button in that if the option is not currently selected, clicking on a checkbox selects the option; if the option is currently selected, clicking on the checkbox deselects the option.

We present two similar examples to illustrate how to use the *RadioButton* and *CheckBox* classes and how they differ. Both examples allow the user to select the background color for a label. We display three color options: red, green, and blue. Using radio buttons, only one color can be selected at a time. Thus, by clicking on a radio button, the user causes the background of the label to be displayed in one of three colors. Using checkboxes, the user can select any combination of the three color options, so the label color can be set to any of eight possible combinations.

We start with the example using radio buttons. The window when the application starts running is shown in **Figure 17.6**.

Figure 17.6 The GUI for the *ChangingColors* Application

Description

We begin with the Model, *ColorSelector.java*, shown in **Example 17.9**. Again, this model is minimal, having only one *static* method, *colorToHexString* (lines 11–25). For convenience in passing parameters, we define three *public static* constants at lines 7 through 9. The controller uses these constants as arguments for the *colorToHexString* method.

Example 17.9 The Model, *ColorSelector.java*

```
/*  ColorSelector class
    Anderson, Franceschi
*/

public class ColorSelector
{
  public static final int RED = 0;
  public static final int GREEN = 1;
  public static final int BLUE = 2;

  /** colorToHexString method
  *  @param selection  the selected color
  *  @return the hex representation of the selec
  */
  public static String colorToHexString( int sel
  {
    String result = "#";
    if ( selection == RED )
      result += "FF0000";
    else if ( selection == GREEN )
      result += "00FF00";
    else if ( selection == BLUE )
      result += "0000FF";
    return result;
  }
}
```

Description

Next, we look at the View, the FXML file that defines the layout and the controls for the GUI, which is shown in **Example 17.10**. For this application, we use an *HBox* layout (lines 6–28), which arranges controls horizontally. We set attributes (line 8) to specify that the controls should be centered with 10 pixels between each control. We also specify the class of the controller that handles the events caused by the user selecting a radio button, as *ChangingColorsController* (line 6).

In order for the radio buttons to be mutually exclusive (i.e., selecting one radio button deselects any previously selected radio button), we define a *ToggleGroup* (lines 10–12). We use the *<fx:define>* element to create objects, such as this *ToggleGroup*, that are not in the scene graph but need to be referenced by a control. In the definition of each radio button (lines 14–22), we add the radio button to the group by setting its *toggleGroup* property to the id of the *ToggleGroup*. We preface the id with "$" to indicate that *colorGroup* is a variable, rather than a predefined property value.

For each radio button, we also use the *onAction* property to specify that the *colorChosen* method in the *ChangingColorsController* should be executed when the user clicks the radio button.

At line 14, we set the red radio button's *selected* property to *true*. This automatically sets the radio button as selected when the program starts.

REFERENCE POINT

To learn more about using CSS for styling controls, read the JavaFX CSS Reference Guide at *https://docs.oracle.com/javafx/2/api/javafx/scene/doc-files/cssref.html*.

Finally, we define the label whose background we color as the user clicks on the radio buttons (lines 24–26). Here we introduce *style* definitions. If you are familiar with Cascading Style Sheets (CSS) used with HTML pages, this should look familiar to you. We explain how to use CSS at the end of this chapter. The *background-color* property sets the background color of a control. Its value can be either a CSS named constant (such as *red*) or the RGB hexadecimal value of the color preceded by a "#" (such as *#FF0000*).

We set the label's background to the color red (*#FF0000*) to be consistent with the *red* radio button being selected when the application starts.

Example 17.10 *fxml_changing_colors.fxml*

```
<?xml version="1.0" encoding="UTF-8"?>

<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>

<HBox fx:controller="ChangingColorsController"
      xmlns:fx="http://javafx.com/fxml"
      alignment="center" spacing="10" >

  <fx:define>
    <ToggleGroup fx:id="colorGroup" />
  </fx:define>

  <RadioButton fx:id="red" text="red" selected="true"
               toggleGroup="$colorGroup"
               onAction="#colorChosen" />
  <RadioButton fx:id="green" text="green"
               toggleGroup="$colorGroup"
               onAction="#colorChosen" />
  <RadioButton fx:id="blue" text="blue"
               toggleGroup="$colorGroup"
               onAction="#colorChosen" />

  <Label fx:id="label" text="Watch my background"
         textFill="WHITE"
         style="-fx-background-color:#FF0000" />

</HBox>
```

Description

Table 17.10 summarizes the special FXML language elements that we have used.

FXML Language Elements and Their Meaning

FXML Element	**Meaning**
fx:define	Used to create objects not in the scene graph that need to be referenced later
FXML Attributes	**Meaning**
fx:id	Defines a name that can be referenced across the FXML application

fx:controller	Defines a class that contains event handling code for one or more controls
onAction	Defines a method name (preceded by “#”) in the controller that should be executed when the user interacts with the control
FXML Annotation	**Meaning**
@FXML	Allows FXML to access a *private* or *protected* class, method, or data
FXML Prefixes	**Meaning**
-fx-	Used to distinguish a JavaFX style attribute from a CSS attribute
$	Used as a prefix to a variable name when the variable is used as a property value
@	Used as a prefix for a URI to specify that the path of the URI starts with the current folder

Description

The Controller, *ChangingColorsController.java*, is shown in **Example 17.11**. At lines 11 through 14, we define instance variables for all the controls, using the *fx:id* values we defined in the FXML file. The *colorChosen* event handler method, defined at lines 16 through 31, takes as a parameter the *ActionEvent* that is generated when the user clicks on a radio button. We want to set the background color of the label to correspond with the radio button that was clicked. Thus, we set the *style* property of the label. We start by setting a *String* to characters that are common for any color selected (line 18). We then use the *getSource* method of the *ActionEvent* to determine which radio button was clicked and call the *colorToHexString* method in our Model, passing as a parameter one of the *public static* constants (*RED*, *GREEN*, or *BLUE*) defined in the Model. We then append the returned hexadecimal *String* to *style*. At line 30, we call the *setStyle* method of the *Label* class, passing it the completed *String*. Note that for any property that can be set using attributes in the FXML file, JavaFX usually also provides accessor and mutator methods in the GUI control’s class for setting or getting the property programmatically.

Example 17.11 The Controller, *ChangingColorsController.java*

```
/*  ChangingColorsController class
    Anderson, Franceschi
*/

import javafx.event.ActionEvent;
import javafx.fxml.FXML;
import javafx.scene.control.*;

public class ChangingColorsController
{
  @FXML private RadioButton red;
  @FXML private RadioButton green;
  @FXML private RadioButton blue;
  @FXML private Label label;

  @FXML protected void colorChosen( ActionEvent event )
  {
    String style = "-fx-background-color: ";

    if ( event.getSource( ) == red )
     style +=
      ColorSelector.colorToHexString( ColorSelector.RED );
    else if ( event.getSource( ) == green )
     style +=
      ColorSelector.colorToHexString( ColorSelector.GREEN );
    else if ( event.getSource( ) == blue )
     style +=
      ColorSelector.colorToHexString( ColorSelector.BLUE );

    label.setStyle( style );
  }
}
```

Description

SOFTWARE ENGINEERING TIP

Ensure that the initial state of the GUI controls represents the state of the Model.

The last part of the application is *ChangingColors*, the launching class, shown in **Example 17.12**. It follows the format of the previous application launching classes.

Example 17.12 The Application Launcher: *ChangingColors.java*

```
/*  Select a Color Using RadioButtons
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.HBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class ChangingColors extends Application
{
  @Override
  public void start( Stage stage )
  {
    try
    {
      URL url =
       getClass( ).getResource( "fxml_changing_colors.fxml" );
      HBox root = FXMLLoader.load( url );
      Scene scene = new Scene( root, 400, 200 );
      stage.setTitle( "Selecting a color" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

We now demonstrate a similar application using *CheckBoxes*. For this example, we create the interface shown in **Figure 17.7**.

Figure 17.7 The GUI for the *MixingColors* Application

Description

Example 17.13 shows the Model, *ColorMixer.java.* The Model's job is to manage the color mixing based on which colors are selected or deselected. As in our *RadioButton* example, the *ColorMixer* also provides *public static* constants (lines 7–9) for the controller's convenience in passing parameters. To manage which colors are selected, the *ColorMixer* defines an array of three *boolean* values (line 11), with each element representing whether the corresponding color is selected *(true)* or deselected (*false*).

Example 17.13 The Model, *ColorMixer.java*

```java
/*  ColorMixer class
    Anderson, Franceschi
*/

public class ColorMixer
{
  public static final int RED = 0;
  public static final int GREEN = 1;
  public static final int BLUE = 2;

  private boolean [ ] rgb;

  /** default constructor
  *   sets all elements in the rgb array to true
  *   to represent the color white
  */
  public ColorMixer( )
  {
    rgb = new boolean[3];
    rgb[RED] = true;
    rgb[GREEN] = true;
    rgb[BLUE] = true;
  }

  /** toggleColor method
  *   toggles the color on/off
  *   @param color  the color to be toggled
  */
  public void toggleColor( int color )
  {
    rgb[color] = !rgb[color];
  }

  /** hexStringColor
  *  @return the hexadecimal representation
  *          of the color mix
  */
  public String hexStringColor( )
  {
    String result = "#";

    result += ( rgb[RED] ? "FF" : "00" );
    result += ( rgb[GREEN] ? "FF" : "00" );
    result += ( rgb[BLUE] ? "FF" : "00" );

    return result;
  }
}
```

Description

The constructor (lines 13–23) instantiates the array and sets all elements to *true*, representing the color white (all colors selected). The *RED*, *GREEN*, and *BLUE* constants also come in handy here as logical names for the array indexes.

The *toggleColor* method (lines 25–32) alternates the state of a color between *true* and *false*. This is consistent with the behavior of *CheckBoxes,* where each click of the *CheckBox* changes its state between selected and deselected.

Finally, the *hexStringColor* method (lines 34–47) composes a *String* containing the hexadecimal equivalent of the current color. Using the conditional operator, we set each color's contribution to the *String* as either *"FF"* (full color) if selected or *"00"* (no color) if deselected.

Next, the FXML file, *fxml_mixing_colors.fxml,* shown in **Example 17.14**, defines the GUI. At lines 11 through 16, we define the three *CheckBoxes* to represent the red, green, and blue color components. We also preselect each *CheckBox* and set the *Label* background to white (line 19) to be consistent with the original state of the Model.

Example 17.14 *fxml_mixing_colors.fxml*

```
 1 <?xml version="1.0" encoding="UTF-8"?>
 2
 3 <?import javafx.scene.control.*?>
 4 <?import javafx.scene.layout.*?>
 5
 6 <HBox fx:controller="MixingColorsController"
 7       xmlns:fx="http://javafx.com/fxml"
 8       alignment="center" spacing="10"
 9       style="-fx-background-color:#CCCCCC" >
10
11   <CheckBox fx:id="red" selected="true"
12             text="red" onAction="#mix" />
13   <CheckBox fx:id="green" selected="true"
14             text="green" onAction="#mix" />
15   <CheckBox fx:id="blue" selected="true"
16             text="blue" onAction="#mix" />
17
18   <Label fx:id="label" text="Watch my background"
19          style="-fx-background-color:#FFFFFF" />
20
21 </HBox>
```

Description

Our controller for this application, *MixingColorsController*, is named at line 6, and we specify that the *mix* method in the controller is the handler for a user selecting or deselecting any of the *CheckBoxes* (lines 12, 14, and 16).

The controller, *MixingColorsController.java,* is shown in **Example 17.15**. The methods in this Model are not *static*, so we define an instance variable, *mixer*, representing the Model (line 11) and the controller instantiates the Model in the constructor (lines 18–21). The *mix* event handler method (lines 23–35) calls the *getSource* method of the *ActionEvent* object to determine which *CheckBox* was clicked. It calls the *toggleColor* method in the Model to invert the state of the color in the *rgb* array. In this way, we do not need to check whether the *CheckBox* was just selected or deselected. Once the clicked color component is updated, we compose the new color *String* by calling the *hexStringColor* method of the model (line 33); then we use that *String* to set the *label*'s background color.

Example 17.15 The Controller, *MixingColorsController.java*

```
/*  MixingColorsController class
    Anderson, Franceschi
*/

import javafx.event.ActionEvent;
import javafx.fxml.FXML;
import javafx.scene.control.*;

public class MixingColorsController
{
  private ColorMixer mixer;

  @FXML private CheckBox red;
  @FXML private CheckBox green;
  @FXML private CheckBox blue;
  @FXML private Label label;

  public MixingColorsController( )
  {
    mixer = new ColorMixer( );
  }

  @FXML protected void mix( ActionEvent event )
  {
    if ( event.getSource( ) == red )
      mixer.toggleColor( ColorMixer.RED );
    else if ( event.getSource( ) == green )
      mixer.toggleColor( ColorMixer.GREEN );
    else if ( event.getSource( ) == blue )
      mixer.toggleColor( ColorMixer.BLUE );

    String style = "-fx-background-color: ";
    style += mixer.hexStringColor( );
    label.setStyle( style );
  }
}
```

Description

The final piece to this application is the standard launch class, shown in **Example 17.16**.

Example 17.16 The Launch Class, *MixingColors.java*

```java
/*  Mixing Colors Using CheckBoxes
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.HBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class MixingColors extends Application
{
  @Override
  public void start( Stage stage )
  {
    try
    {
      URL url =
         getClass( ).getResource( "fxml_mixing_colors.fxml" );
      HBox root = FXMLLoader.load( url );
      Scene scene = new Scene( root, 400, 200 );
      stage.setTitle( "Mixing colors" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

17.7 Programming Activity 1: Working with Buttons

In this activity, you will work with two *Buttons* that control a simulated electrical switch. Specifically, you will write the code to perform the following operations:

1. If the user clicks on the “OPEN” button, open the switch.
2. If the user clicks on the “CLOSE” button, close the switch.

The framework for this Programming Activity will animate your code so that you can check its accuracy. **Figures 17.8** and **17.9** show the application after the user has clicked the button labeled “OPEN” and the button labeled “CLOSE,” respectively.

Figure 17.8 User Clicked “OPEN”

Description

Figure 17.9 User Clicked “CLOSE”

Description

Instructions

Copy the source files in the Programming Activity 1 folder for this chapter to a folder on your computer. Note that all files should be in the same folder.

Open the *fxml_button_practice.fxml* file. Searching for five asterisks (*****) in the source code will position you to the first code section and then to the second location where you will add your code. In task 1, you will specify the name of the controller as *ButtonPracticeController*. In task 2, you will define an *HBox* layout with the two buttons. **Example 17.17** shows the section of the *fxml_button_practice.fxml* file where you will add your code.

Example 17.17 Location of Student Code in *fxml_button_practice.fxml*

```
<?xml version="1.0" encoding="UTF-8"?>

<?import javafx.scene.*?>
<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>

<!-- ***** 1. Student code starts here -->
<!-- add the code to this element definition to specify
     the controller as ButtonPracticeController -->
<BorderPane fx:id="bp"
            xmlns:fx="http://javafx.com/fxml" >

  <top>
    <!-- ***** 2. Student code restarts here -->
    <!-- add code to define an HBox layout that is centered
         with an id of hBox and 10 pixels between controls.
         Inside the HBox, add 2 Buttons, with text OPEN and
         CLOSE, and ids of open and close. Clicking on either
         button triggers a call to the event handler flip
         method -->

  </top>

</BorderPane>
```

Description

Note that we define an *HBox* layout container inside a *BorderPane* layout container, illustrating that layouts can be nested. We demonstrate nested layouts again later in the chapter.

Next, open *ButtonPracticeController.java* and search for five asterisks (*****). This will position you at the third and final task for this Programming Activity, writing the event handler for the buttons. **Example 17.18** shows the section of the source code where you will add your code.

Example 17.18 Location of Student Code in *ButtonPracticeController.java*

```
// ***** 3. Student code restarts here
// Code the flip method.
// To open the switch, call the open method
//   with circuit, the object reference of the
//   Circuit object.
//   The open method does not take any parameters.
// To close the switch, call the close method
//   with circuit.
//   The close method does not take any parameters.
// The last statement of the method should be
//   animate( );
```

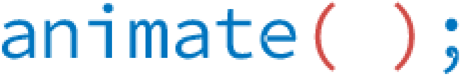
Description

Our framework will animate your code so that you can watch your code work. For this to happen, be sure that you call the *animate* method as the last statement in the *flip* method.

Troubleshooting

If your *flip* method does not animate, check these tips:

- Verify that the last statement in your *flip* method is:

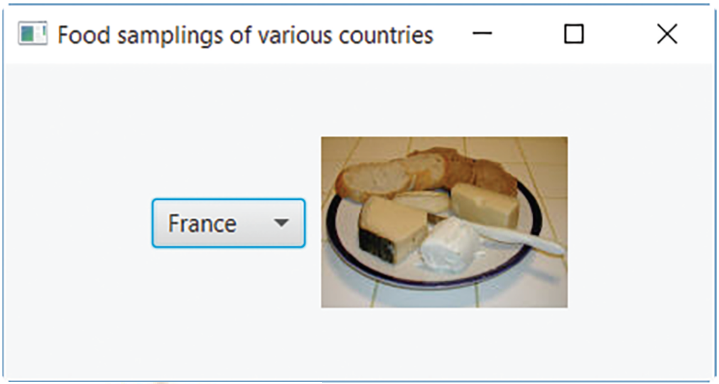


```
animate( );
```

- Verify that your listener is registered on the buttons (*onAction*).
- Verify that you have correctly identified the button that fired the event using the *getSource* method.

DISCUSSION QUESTIONS

1. Explain why the *getSource* method is useful here.
2. Could you implement this application with *RadioButtons* instead of *Buttons*? What definition would you need to add to the *FXML* file? How would the *flip* method change, if at all?
3. Which class is the Model?



17.8 Combo Boxes

A *ComboBox* implements a drop-down list. When the combo box appears, either no item or one item is displayed, along with a down arrow icon. When the user presses on the down arrow, the combo box “drops” open and displays a list of items, with a scroll bar for viewing more items. The user can select one item from the list. When the user selects an item, the list closes and only the selected item is displayed.

In this example, we allow the user to select a country from a combo box, and in response, we display an image of a typical food from the selected country. **Figure 17.10** shows the window when our application begins.

Figure 17.10 The Food Sampling Application

Description

We begin as usual with the Model, *FoodSampler.java*, shown in **Example 17.19**. Lines 9 through 16 define two arrays. The *countryList* array contains the country names to be displayed in the *ComboBox*, and the *foods* array contains the corresponding images of food stored in the same order as the country names. The instance variable *selectedInde*x, defined at line 17, holds the index of the selected country. We use this index to retrieve the appropriate food image to display. With s*electedIndex* set to 0, the Model's initial state is that the country name "France" is selected and *cheese.jpg* is the corresponding image.

Example 17.19 The Model, *FoodSampler.java*

```java
/*  FoodSampler class
    Anderson, Franceschi
*/

import javafx.scene.image.Image;

public class FoodSampler
{
  private String [ ] countryList =
     { "France", "Greece", "Italy", "Japan", "USA" };
  private Image [ ] foods =
     { new Image( "cheese.jpg" ),
       new Image( "fetasalad.jpg" ),
       new Image( "pizza.jpg" ),
       new Image( "sushi.jpg" ),
       new Image( "hamburger.jpg" ) };
  private int selectedIndex = 0;

  /** getCountryList method
  *  @return a reference to the countryList array
  */
  public String [ ] getCountryList( )
  {
    return countryList;
  }

  /** the accessor for selectedIndex
  *  @return the index selected
  */
  public int getSelectedIndex( )
  {
    return selectedIndex;
  }

  /** the mutator for selectedIndex
  * @param selection the new value for selectedIndex
  */
  public void updateSelection( int selection )
  {
    selectedIndex = selection;
  }

  /** the accessor for the image to display
  *  @return the image from the Image array
  *          using the index selectedIndex
  */
  public Image getImageSelected( )
  {
    return foods[selectedIndex];
  }
}
```

Description

The remainder of the Model consists of accessor methods for the *countryList* array (lines 19–25) and *selectedIndex* (lines 27–33), a mutator method for *selectedIndex* (lines 35–41), and an accessor for the image corresponding to *selectedIndex* (lines 43–50).

Next we look at the FXML file, *fxml_food_samplings.fxml,* shown in **Example 17.20**. At line 7, we identify the Controller as *FoodSamplingsController.java*. Lines 11 through 13 define our *ComboBox* control and that the *itemSelected* method in the Controller class will handle the event fired by a user selecting an item from the *ComboBox* drop-down list. We also set the *visibleRowCount* property to 3, specifying that when the user opens the *ComboBox*, three items should be displayed along with a scrollbar for viewing the other hidden items. The default value for the *visibleRowCount* property is 10. If the list contains fewer items than specified in the *visibleRowCount* property, the *ComboBox* displays all the items in the list.

Example 17.20 The *fxml_food_samplings.fxml File*

```
 1 <?xml version="1.0" encoding="UTF-8"?>
 2
 3 <?import javafx.scene.control.*?>
 4 <?import javafx.scene.image.*?>
 5 <?import javafx.scene.layout.*?>
 6
 7 <HBox fx:controller="FoodSamplingsController"
 8       xmlns:fx="http://javafx.com/fxml"
 9       alignment="center" spacing="10" >
10
11   <ComboBox fx:id="countries" visibleRowCount="3"
12             onAction="#itemSelected" >
13   </ComboBox>
14
15   <ImageView fx:id="foodImage">
16   </ImageView>
17
18 </HBox>
```

Description

At lines 15 and 16 we also define an *ImageView* control to display the appropriate food image. We do not specify the initial image here; we let the Controller get the appropriate image from the Model.

We turn now to the Controller, *FoodSamplingsController.java*, shown in **Example 17.21**. New to this Controller is the *initialize* method, which is called after the scene graph has been created, and can be used to add items to the scene graph that could not be fully defined in the FXML file. Because the Model stores the list of countries and corresponding images, we cannot specify the items for *ComboBox* in the FXML file. However, this approach also has some advantages: By adding the items to the *ComboBox* at runtime, we can easily handle changes in the list without needing to change our Controller or FXML code, and we can use this application with another Model that has a different set of items and images.

Example 17.21 The Controller, *FoodSamplingsController.java*

```
 1 /*  FoodSamplingsController class
 2     Anderson, Franceschi
 3 */
 4
 5 import javafx.event.ActionEvent;
 6 import javafx.fxml.FXML;
 7 import javafx.scene.control.*;
 8 import javafx.scene.image.*;
 9
10 public class FoodSamplingsController
11 {
12   private FoodSampler sampler;
13
14   @FXML private ComboBox<String> countries;
15   @FXML private ImageView foodImage;
16   private SingleSelectionModel<String> selectionModel;
17
18   public void initialize( )
19   {
20    sampler = new FoodSampler( );
21
22    // populate combobox with data from the Model
23    countries.getItems( ).addAll( sampler.getCountryList( ) );
24
25    // get a reference to the SingleSelectionModel
26    selectionModel = countries.getSelectionModel( );
27
28    // initialize View with initial data from Model
29    selectionModel.select( sampler.getSelectedIndex( ) );
30    foodImage.setImage( sampler.getImageSelected( ) );
31   }
32
33   @FXML protected void itemSelected( ActionEvent event )
34   {
35    // retrieve index of country selected
36    int index = selectionModel.getSelectedIndex( );
37    // update the Model
38    sampler.updateSelection( index );
39    // update the View with Image from the Model
40    foodImage.setImage( sampler.getImageSelected( ) );
41   }
42 }
```

Description

A *ComboBox* control is a generic class, so when the Controller defines the *ComboBox* (line 14), we need to specify the class type of the items to be displayed; in this example, we are displaying *Strings*.

A *ComboBox*, like other controls that allow users to select items, uses a *SelectionModel* to handle the user's interactions with the control. The *ComboBox* uses the

SingleSelectionModel, which is a subclass of *SelectionModel*, to restrict the user to a choice of only one item from the list. The *SingleSelectionModel* class is also a generic class; thus, we specify the class type to be *String* in line 16. **Table 17.11** shows some useful methods of the *SingleSelectionModel* class for setting and getting the user's selection.

Useful Methods of the *SingleSelectionModel* Class

Package	**javafx.scene.control**
Return value	**Method name and argument list**
`int`	`getSelectedIndex( )`
returns the index of the currently selected item.	
`T`	`getSelectedItem( )`
returns the currently selected item.	
`void`	`select( int index )`
selects the item at *index*. Any previously selected item is deselected.	

Description

In order for our Controller event handler method, *itemSelected,* to be notified when the user selects an item, we need to put our items into an *ObservableList* object. **Table 17.12** shows the *getItems* method of the *ComboBox*, which returns an *ObservableList*. The *addAll* method of the O*bservableList* class, shown in **Table 17.13**, can be used to insert items into the list. The *addAll* method uses the *varargs* syntax to accept a variable number of arguments.

A Useful Method of the *ComboBox<T>* Class

Package	**javafx.scene.control**
Return value	**Method name and argument**

	list
`ObservableList`	`getItems( )`
returns the values of the items in the *ComboBox* as an *ObservableList*	

Description

A Useful Method of the *ObservableList<E>* Interface

Package	**javafx.collections**
Return value	**Method name and argument list**
`boolean`	`addAll( E... elements )`
adds the elements to the list	

Description

Putting this all together, in the *initialize* method, we instantiate the Model (line 20), and then call the *getItems* method, which returns an empty *ObservableList.* Next, we call the *addAll* method of the *ObservableList* class to insert into the *ComboBox* the array of country names returned by the Model's *getCountryList* method (lines 22–23).

At line 26, we get a reference to the *SingleSelectionModel*; we then use that reference to select the item using the index returned from the Model's *getSelectedIndex* method (line 29). At this point, the value returned will be 0, because in the Model, we initialize the *selectedIndex* instance variable to 0. We then set the image for our *foodImage ImageView* to the filename returned by the Model's *getImageSelected* method (line 30). Thus, when the window first appears, the country *France* is selected and we display the *cheese.jpg* image.

The *itemSelected* event handler, which executes whenever the user selects a new item from the *ComboBox* (lines 33–41), retrieves the index of the selected item by calling the *getSelectedIndex* method, using the *selectionModel* reference. Using that index, we notify the model that the user has changed the selection. Then we determine which new image to display by calling the Model's *getImageSelected* method.

The last piece of the application is the launch class, shown in **Example 17.22**.

Example 17.22 *FoodSamplings.java*

```java
/*  Using ComboBox to show a sampling of international foods
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.HBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class FoodSamplings extends Application
{
  @Override
  public void start( Stage stage )
  {
   try
   {
     URL url =
        getClass( ).getResource( "fxml_food_samplings.fxml" );
     HBox root = FXMLLoader.load( url );
     Scene scene = new Scene( root, 450, 200 );
     stage.setTitle( "Food samplings of various countries" );
     stage.setScene( scene );
     stage.show( );
   }
   catch ( Exception e )
   {
     e.printStackTrace( );
   }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

CODE IN ACTION

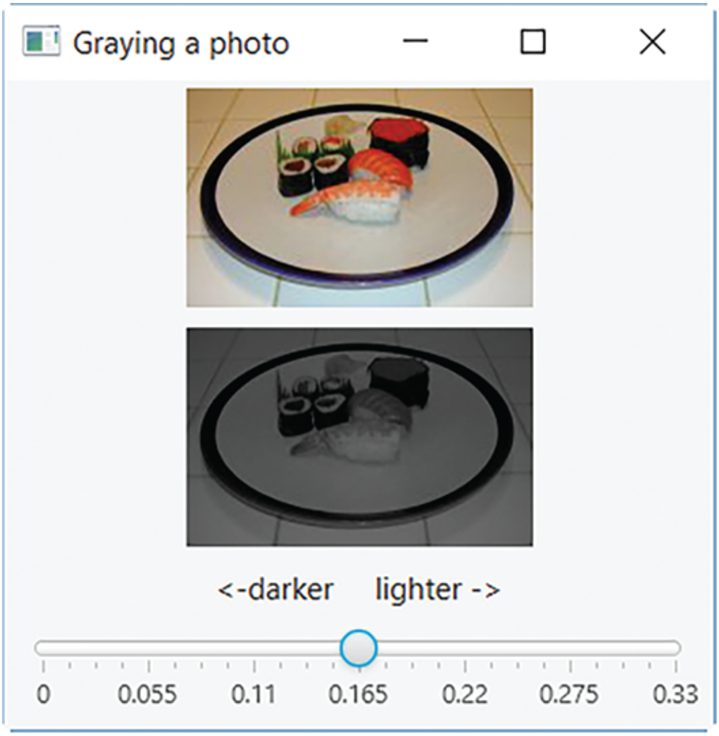
step-by-step illustration of working with GUI components. Click on the link to start the movie.

© Hemera Technologies/Photos.com/Thinkstock



17.9 Sliders

The *Slider* control is capable of displaying a set of continuous values along a horizontal or vertical line, called a **track**. The user "slides" the knob, called the **thumb**, along the track to select a value from the set. To illustrate the *Slider* control, we create an application that allows the user to control the level of gray in a photo. A gray color is created when the red, green, and blue components have the same value. Each color component's value can range from 0.0 to 1.0.

Figure 17.11 shows the GUI when the application begins. The top photo is the original version of the image; this may look familiar as the *sushi.jpg* photo from the *ComboBox* example in the last section. The lower photo has been converted to a middle level of gray. As the user slides the knob left, we darken the photo; as the user slides the knob to the right, we lighten the photo. The vertical lines and numbers shown under the slider are **tick marks** and **tick values.** The values represent a multiplier we use to convert the red, green, and blue color values of the photo to a new level of gray.

Figure 17.11 The Photo Graying GUI

Description

We define the *Slider* control in the FXML file, shown in **Example 17.23.** At lines 20 through 23, we specify the minimum multiplier value as 0, the maximum as .33, and the initial value in the middle of that range as .165. We set properties to show the tick marks and tick labels and to display the tick marks at intervals of .055 units.

Example 17.23 The View, *fxml_photo_grayer.fxml*

```
 1 <?xml version="1.0" encoding="UTF-8"?>
 2
 3 <?import javafx.scene.control.*?>
 4 <?import javafx.scene.image.*?>
 5 <?import javafx.scene.layout.*?>
 6
 7 <VBox fx:controller="PhotoGrayerController"
 8     xmlns:fx="http://javafx.com/fxml"
 9     alignment="center" spacing="10"
10     style="-fx-padding:0 10 0 10;" >
11
12   <ImageView fx:id="originalImageView" >
13     <Image url = "Sushi.jpg" />
14   </ImageView>
15
16   <ImageView fx:id="grayImageView" />
17
18   <Label text="&lt;-darker lighter -&gt;" />
19
20   <Slider fx:id="slider" min="0" max=".33"
21           value=".165" showTickMarks="true"
22           showTickLabels="true" majorTickUnit="0.055" />
23
24 </VBox>
```

Description

COMMON ERROR TRAP

Be sure to use the XML and FXML encoding sequences when specifying text values that contain characters having syntactic meaning in XML and FXML. Otherwise, the FXML Loader will generate an error.

In line 10, we add a *style* property to define padding values for the *VBox*. We add 10 pixels of padding on the left and right sides of the *VBox,* but no padding on the top and bottom.

SOFTWARE ENGINEERING TIP

Labels can help guide the user through the interface.

The *Label* control defined at line 18 aids the user by showing that moving the thumb to the left will darken the image and moving the thumb to the right will lighten the image. Because angle brackets have syntactic meaning in FXML, we use the special character encoding sequences *&lt;* and *&gt;* to represent the left and right angle brackets, respectively. **Table 17.14** shows the encoding sequences for the XML and FXML special characters. The five XML encoding sequences start with an ampersand and end with a semicolon. In addition, FXML adds three special characters; the encoding sequences for these FXML special characters consist simply of a leading backslash followed by the special character. These encoding sequences are useful whenever a control's text value contains any of these special characters as data.

XML and FXML Special Characters

Character	**XML Encoding Sequence**
<	&lt;
>	&gt;
&	&amp;
"	&quot;
'	&apos;
Character	**FXML Encoding Sequence**

Description

By looking at the Model (**Example 17.24**), we can see how the *Slider's* multiplier values are used to adjust the image's color. The Model, *PhotoGrayer.java,* extends the *Image* class, which is used to load graphical images (GIF, BMP, JPG, and PNG) from a URL. In our constructor (lines 13–21), we pass the image filename to the constructor of the *Image* superclass, shown in **Table 17.15**.

Example 17.24 The Model, *PhotoGrayer.java*

```java
/*  Adjusts the gray value of an image
    Anderson, Franceschi
*/

import javafx.scene.image.Image;
import javafx.scene.image.PixelReader;
import javafx.scene.image.PixelWriter;
import javafx.scene.image.WritableImage;
import javafx.scene.paint.Color;

public class PhotoGrayer extends Image
{
  /** constructor
  * @param file  filename of the image
  *    passes the filename to the Image class
  *    constructor
  */
  public PhotoGrayer( String file )
  {
    super( file );
  }

  /** gray method
  *  @param coeff the multipler to determine the
  *          color for each pixel
  *  @return a WritableImage
  */
  public WritableImage gray( double coeff )
  {
    int width = ( int ) getWidth( );
    int height = ( int ) getHeight( );
    WritableImage grayImage
         = new WritableImage( width, height );
    PixelWriter pw = grayImage.getPixelWriter( );
    PixelReader pr = getPixelReader( );

    for ( int x = 0; x < width; x++ )
    {
      for ( int y = 0; y < height; y++ )
      {
        Color currentColor = pr.getColor( x, y );
        double grayValue =  coeff *
          ( currentColor.getRed( ) + currentColor.getGre
            + currentColor.getBlue( ) );
        currentColor = Color.gray( grayValue );
        pw.setColor( x, y, currentColor );
      }
    }
    return grayImage;
  }
}
```

Description

A Constructor and Useful Methods of the *Image* Class

Package	**javafx.scene.image**
Constructor	
`Image( String URL )`	
constructs an *Image* from the file named in *URL*	
Return value	**Method name and argument list**
`PixelReader`	`getPixelReader( )`
returns a *PixelReader* object for accessing the pixels in the *Image*	
`double`	`getHeight( )`
returns the height of the image in pixels	
`double`	`getWidth( )`
returns the width of the image in pixels	

Description

The purpose of the *gray* method (lines 23–50) is to create an image composed of varying levels of gray. The gray level of each pixel in the new image is computed by multiplying the red, green, and blue components of the corresponding pixel in the original image by the parameter *coeff*.

Let's look at the *gray* method in detail. To get the size of the image, we call the *getWidth* and *getHeight* methods, shown in Table 17.15, which we have inherited from the *Image* class. Using this information, we create an empty *WritableImage* object of the same size. A *WritableImage* object can be used to create an image from pixels. **Table 17.16** shows the constructor and useful methods of the *WritableImage* class, which also inherits from the *Image* class.

A Constructor and a Useful Method of the *WritableImage* Class

Package	**javafx.scene.image**

Constructor	
`WritableImage( int width, int height )`	
constructs an empty WritableImage of the specified width and height	
Return value	**Method name and argument list**
`PixelWriter`	`getPixelWriter( )`
returns a *PixelWriter* object for writing the pixels in the *Image*	

Description

We then use the *getPixelWriter* factory method (line 34) to obtain a *PixelWriter* object to write pixel data into the *WritableImage.*

At line 35, we call the *getPixelReader* factory method to get a *PixelReader* object to read pixel data from the original image. A *PixelReader* object provides access to each pixel in the original image (see **Table 17.17**), while a *PixelWriter* object allows us to set the color of each pixel in the *WritableImage* (see **Table 17.18**).

A Method of the *PixelReader* Interface

Package	**javafx.scene.image**
Return value	**Method name and argument list**
`Color`	`getColor( int x, int y )`
returns the *Color* of the pixel at coordinate (*x*, *y*) in the image	

Description

A Method of the *PixelWriter Interface*

Package	**javafx.scene.image**

Return value	**Method name and argument list**
`void`	`setColor( int x, int y, Color c )`
sets the pixel at coordinate (*x*, *y*) to the color *c*	

Description

Using a nested *for* loop (lines 37–48), we use that *PixelReader* reference to move through each pixel in the original image. We first retrieve the color of each pixel by calling the *getColor* method of the *PixelReader*, passing it the current *x* and *y* values (lines 40–41).

Using the current color of the original image, we then multiply the sum of the red, green, and blue components by the *coeff* parameter (lines 42–44) and pass the resulting value to the *gray* method of the *Color* class (line 45); this returns a *Color* object where the red, green, and blue components have the *grayValue* parameter's value. The methods of the *Color* class that we use in this example are shown in **Table 17.19**. Finally, we use the *PixelWriter* to set the color of the corresponding pixel within the *WritableImage* (line 46) to the newly computed gray color.

Useful Methods of the *Color* Class

Package	**javafx.scene.paint**
Return value	**Method name and argument list**
`double`	`getRed( )`
returns the red component of the color in the range 0.0–1.0	
`double`	`getGreen( )`
returns the green component of the color in the range 0.0–1.0	
`double`	`getBlue( )`
returns the blue component of the color in the range 0.0–1.0	
`Color`	`gray( double value )`
returns a *Color* object where the red, green, and blue components are set to *value,* which can range from 0.0 to 1.0	

Description

We return the new image at line 49.

The Controller, *PhotoGrayerController.java,* shown in **Example 17.25**, handles any changes to the *Slider*'s value made by the user dragging the thumb in either direction. In the *initialize* method (lines 14–25), we instantiate the Model (line 16), sending the filename of the photo to the constructor.

Example 17.25 The Controller, *PhotoGrayerController.java*

```
 1 import javafx.beans.value.*;
 2 import javafx.event.*;
 3 import javafx.fxml.FXML;
 4 import javafx.scene.control.*;
 5 import javafx.scene.image.*;
 6
 7 public class PhotoGrayerController
 8 {
 9   private PhotoGrayer photoGrayer;
10
11   @FXML private ImageView grayImageView;
12   @FXML private Slider slider;
13
14   public void initialize( )
15   {
16     photoGrayer = new PhotoGrayer( "sushi.jpg" );
17
18     // initialize grayImageView
19     Image grayImage = photoGrayer.gray( slider.getValue( ) );
20     grayImageView.setImage( grayImage );
21
22     // set up event handling for slider
23     SliderHandler sh = new SliderHandler( );
24     slider.valueProperty( ).addListener( sh );
25   }
26
27   private class SliderHandler
28                implements ChangeListener<Number>
29   {
30     @Override
31     public void changed( ObservableValue<? extends Number> o,
32                          Number oldValue, Number newValue )
33     {
34       // update grayImageView
35       grayImageView.setImage(
36              photoGrayer.gray( newValue.doubleValue( ) ) );
37     }
38   }
39 }
```

Description

At lines 18 through 20, we initialize the second photo by calling the *gray* method in the Model, sending it the current slider value by calling the *getValue* method of the *Slider* class, as shown in **Table 17.20**.

Some Useful Methods of the *Slider* Class

Package	**javafx.scene.control**
Return value	**Method name and argument list**
`double`	`getValue( )`
returns the current value of the *Slider* as a *double*	
`DoubleProperty`	`valueProperty( )`
returns the current value of the *Slider* as a *DoubleProperty*, which is a *Property* wrapper class for a *double*, and implements the *ObservableValue<Number>* interface	

Description

The final initialization task is to register the event handler for the *Slider* control. Before we cover that, let's look at lines 27 through 38, where we define the event handler as a *private* **inner class** named *SliderHandler*. A *private* inner class is defined inside a *public* class and has access to all the members of the *public* class. Thus, declaring our event handler as a *private* inner class simplifies our code by giving the event handler direct access to our application's GUI components.

Similar to the *ComboBox*, for which we set up an *ObservableList*, the slider value is an *ObservableValue*, meaning that we can register an event handler that will be notified when the value changes. The *SliderHandler* class implements the *ChangeListener* interface, which has one method that we must override, shown in **Table 17.21** and here:

The Method of the *ChangeListener < T >* Interface

Package	**javafx.beans.value**
Return value	**Method name and argument list**
`void`	`changed( ObservableValue<? extends T> observable, T oldValue, T newValue)`

The *ChangeListener* must implement this method to handle changes to the *ObservableValue*.

Description

```
void changed( ObservableValue<? extends T> observable,
              T oldValue, T newValue )
```

Description

The syntax *<? extends T>* means that the observable value can be of any type that is a subclass of the generic type *T* or the type *T* itself. At lines 30 through 37, where we override the method above, we specify the *T* parameter to be *Number* (in *java.lang*), which is an *abstract* superclass extended by Java's numeric wrapper classes: *Byte*, *Short*, *Integer*, *Long*, *Float*, and *Double.* This works because our observable value is a *Double.*

Inside the method, we set the new color for the *ImageView grayImageView* by calling the *gray* method of the Model and sending it the new value of the *Slider*, obtained by calling the *doubleValue* method of the *Double* class, shown in **Table 17.22**.

A Useful Method of the *Double* Class

Package	**java.lang**
Return value	**Method name and argument list**
`double`	`doubleValue( )`

abstract method in the *Number* class overridden by the *Double* class; it returns the value of a *Double* object as a *double*

Description

Now we're ready to look at lines 23 and 24. At line 23, we instantiate an object of the *SliderHandler* inner class. At line 24, we call the *valueProperty* method of the *Slider* class (shown in Table 17.20), which returns the value of the *Slider* as a *DoubleProperty* object. Because the *DoubleProperty* class implements the *ObservableValue* interface, we can call the *addListener* method of that class to register our event handler. The *ObservableValue* interface, shown in **Table 17.23**, is also generic. The syntax *<? super T>* means that the observable value can be of any type that is a superclass of the generic type *T* or the type *T* itself.

The Methods of the *ObservableValue*<T> Interface

Package	**javafx.beans.value**
Return value	**Method name and argument list**
`void`	`addListener( ChangeListener<? super T> listener )`
adds a *ChangeListener* whose code will execute whenever the value of the *ObservableValue* changes	
`T`	`getValue( )`
returns the current value of the *ObservableValue* object	
`void`	`removeListener( ChangeListener<? super T> listener )`
removes the listener so that it is no longer notified of changes to the value of the *ObservableValue*	

Description

The last piece of the application is the launch class, shown in **Example 17.26**.

Example 17.26 *PhotoGraying.java*

```
/*  Slider demo
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.VBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class PhotoGraying extends Application
{
  @Override
  public void start( Stage stage )
  {
    try
    {
      URL url =
        getClass( ).getResource( "fxml_photo_grayer.fxml" );
      VBox root = FXMLLoader.load( url );
      Scene scene = new Scene( root, 350, 320 );
      stage.setTitle( "Graying a photo" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

17.10 Building a GUI Programmatically

We have been defining GUIs using FXML, which works well when we know the number and type of controls in our GUI. Sometimes, however, the GUI is dynamic and because we may not know how many buttons or other controls we need until runtime, we must define the GUI, that is, instantiate the controls and set their properties, programmatically. For example, the GUI may include buttons that represent URL links stored in a file or on a web server. In that case, the number of buttons can vary each time we run our application. In other applications, it may be more convenient to build the GUI by code rather than with FXML. For example, if the GUI represents a tic-tac-toe game or a chessboard, it is convenient to represent the GUI as a two-dimensional array of buttons, which we define and instantiate programmatically.

We illustrate this approach with an example where we build a chessboard and reveal the position of a square as its column letter and row number when the user clicks on it. **Figure 17.12** shows the application running after the user has clicked on several buttons.

Figure 17.12 Running the Chessboard Example

Description

Before defining the View and the Controller, we define our Model, the *BoardGame* class, shown in **Example 17.27**. We define a board with an array of *chars* representing the column letters and an array of *ints* representing the row numbers. We declare two instance variables for these arrays at lines 12 and 13. We include an array of colors (line 14) so that clients of this class can use custom colors for the board. The *getSquareText* method (lines 29–37) returns a *String* representation of a square on the board as the concatenation of the letter and digit at the row and column indexes requested by the two parameters.

Example 17.27 The *BoardGame* Class

```java
/*  BoardGame class
    Anderson, Franceschi
*/

import javafx.scene.paint.Color;

public class BoardGame
{
  private static char [ ] hexDigits =
         { '0', '1', '2', '3', '4', '5', '6', '7', '8', '9',
           'A', 'B', 'C', 'D', 'E', 'F' };
  private int [ ] rows;
  private char [ ] columns;
  private Color [ ] colors; // to color the rows and columns

  /** Overloaded Constructor
  *  @param newRows     the row numbers
  *  @param newColumns  the column letters
  *  @param newColors   the colors
  */
  public BoardGame( int [ ] newRows, char [ ] newColumns,
                    Color [ ] newColors )
  {
    rows = newRows;
    columns = newColumns;
    colors = newColors;
  }

  /** getSquareText method
  *  @param row      the row index
  *  @param column   the column index
  *  @return a String, a concatenation of columns[column] and rows[row]
  */
  public String getSquareText( int row, int column )
  {
    return String.valueOf( columns[column] ) + rows[row];
  }

  /** getSquareColor method
  *  @param row      the row index
  *  @param column   the column index
  *  @return a String, a hex representation of
  *                    colors[(row + col) % colors.length]
  */
  public String getSquareColor( int row, int col )
  {
    Color squareColor = colors[(row + col) % colors.length];
    return toHexString( squareColor );
  }

  /** toHex utility method
  *  @param colorIntensity   a double between 0 and 1 inclusive
  *  @return a String, the hex representation of colorIntensity times 255
  */
  public String toHex( double colorIntensity )
  {
    int colorIntensityAsInt = ( int ) ( colorIntensity * 255 );
    if ( colorIntensityAsInt > 255 )
      colorIntensityAsInt = 255;
    else if ( colorIntensityAsInt < 0 )
      colorIntensityAsInt = 0;

    int firstDigit = colorIntensityAsInt / 16;
    int secondDigit = colorIntensityAsInt % 16;

    return String.valueOf( hexDigits[firstDigit] ) + hexDigits[secondDigit];
  }

  /** toHexString method
  *  @param color  a Color
  *  @return a String, a hex representation of color
  */
  public String toHexString( Color color )
  {
    String colorText = "#" + toHex( color.getRed( ) )
                           + toHex( color.getGreen( ) )
                           + toHex( color.getBlue( ) );
    return colorText;
  }

  /** getNumberOfRows method
  *  @return the number of rows
  */
  public int getNumberOfRows( )
  {
    return rows.length;
  }

  /** getNumberOfColumns method
  *  @return the number of columns
  */
  public int getNumberOfColumns( )
  {
    return columns.length;
  }
}
```

Description

The *getSquareColor* method (lines 39–49) returns a hexadecimal representation of the color of the square on the board given its row and column numbers, which are sent as parameters to the method. This method can be used to color the board with alternating colors retrieved from the array *colors*.

We provide accessors for the number of rows and the number of columns (lines 81–87 and 89–95).

Even though we are defining the GUI by code, it is possible to separate the View class from the Controller class, as in the previous examples. However, in order to keep this example simple, we put the View and the Controller in the same class.

Regardless of the layout container used, the constructor of our application needs to perform the following operations:

- Instantiate components
- Add components to the layout container

For this example, we use a *GridPane* layout container that allows us to arrange components in a grid. We can visualize a *GridPane* as a table made up of cells in rows and columns. Each cell can contain one component. These cells can have different sizes. In this application, as in many, however, each cell has the same size. Components are placed on the grid at a specified column and row using one of the *add* methods of the *GridPane* class, such as the one shown in **Table 17.24**. Note that the column parameter is given before the row parameter.

Useful Methods of the *GridPane* Class

Package	**javafx.scene.layout**
Return value	**Method name and argument list**
`void`	`add( Node child, int columnIndex, int rowIndex )`
adds *child* to this *GridPane* at row *rowIndex* and column *columnIndex*	
`ObservableList<RowConstraints>`	`getRowConstraints( )`

returns a list of row constraints for this *GridPane*	
`ObservableList<ColumnConstraints>`	`getColumnConstraints( )`
returns a list of column constraints for this *GridPane*	

Description

By default, the rows and columns in the grid are sized to their preferred size, which is based on the content of each cell and independent of the size of the *GridPane*. A *GridPane* maintains lists of row and column constraints that it uses to size each cell in the grid. There are no row or column constraints when a *GridPane* is first instantiated, so these two lists are originally empty. If we want to control the height of each row in the grid, we add as many row constraints as there are rows in the grid; similarly, if we want to control the width of each column in the grid, we add as many column constraints as there are columns in the grid. In this example, we want all the rows to have the same height and all the columns to have the same width. We also want all the cells to fill the space in the *GridPane*.

The *getRowConstraints* and *getColumnConstraints* methods of the *GridPane* class, shown in Table 17.24, retrieve the list of row and column constraints, respectively.

We use the *add* method of the *ObservableList* interface, inherited from the *List* interface, to add a row or a column constraint to the appropriate list. When we add a constraint to the list of row or column constraints, it is automatically added to the list of constraints in the *GridPane*. This method is shown in **Table 17.25**.

The *add* and *clear* Methods of the *List* Interface

Package	**java.util**
Return value	**Method name and argument list**
`boolean`	`add( E e )`
appends *e* to the end of the list	
`void`	`clear( )`

removes all the elements from the list

Description

The *RowConstraints* and *ColumnConstraints* classes can be used to define the height of a row and width of a column in a *GridPane*, respectively. Often, we want to set the dimensions of a row or column as a percentage of the available space within the *GridPane*. We do this with the *setPercentHeight* and *setPercentWidth* methods of the *RowConstraints* and *ColumnConstraints* classes. These methods are shown in **Tables 17.26** and **17.27**.

The *setPercentHeight* Method of the *RowConstraints*

Package	**javafx.scene.layout**
Return value	**Method name and argument list**
`void`	`setPercentHeight( double value )`

sets the height of a row as a percentage of the total height of the *GridPane*

Description

The *setPercentWidth* Method of the *ColumnConstraints* Class

Package	**javafx.scene.layout**
Return value	**Method name and argument list**
`void`	`setPercentWidth( double value )`

sets the width of a column as a percentage of the total width of the

Description

Example 17.28 shows how to define a GUI by code using a *GridPane* to display a chessboard. Each position on a chessboard is identified by a letter (a–h) and a number (1–8). From the standpoint of the white player, the lower left square is a1, and from the standpoint of the black player, the lower left square is h8. When the user clicks on a square on the chessboard, our application displays its position.

Example 17.28 The *BoardView* Class

```
/*  Using GridPane to organize our window
    Anderson, Franceschi
*/

import javafx.event.ActionEvent;
import javafx.event.EventHandler;
import javafx.scene.control.Button;
import javafx.scene.layout.*;

public class BoardView extends GridPane
{
  private BoardGame game;
  private Button [ ][ ] squares;

  public BoardView( BoardGame newGame )
  {
    super( );
    game = newGame;

    // set up grid according to Model
    int rows = game.getNumberOfRows( );
    int columns = game.getNumberOfColumns( );
    RowConstraints row = new RowConstraints( );
    row.setPercentHeight( 100.0 / rows );
    ColumnConstraints col = new ColumnConstraints( );
    col.setPercentWidth( 100.0 / columns );
    for ( int i = 0; i < rows; i++ )
      getRowConstraints( ).add( row );
    for ( int j = 0; j < columns; j++ )
      getColumnConstraints( ).add( col );

    squares = new Button[rows][columns];
    ButtonHandler bh = new ButtonHandler( );

    for ( int i = 0; i < rows; i++ )
    {
      for ( int j = 0; j < columns; j++ )
      {
        // instantiate the button with no text
        squares[i][j] = new Button( );

        // color the button
        squares[i][j].setStyle( "-fx-background-color:"
          + game.getSquareColor( i, j ) );

        // add the button
        add( squares[i][j], j, i );

        // make button fill up available width and height
        squares[i][j].setMaxWidth( Double.MAX_VALUE );
        squares[i][j].setMaxHeight( Double.MAX_VALUE );

        // register listener on button
        squares[i][j].setOnAction( bh );
      }
    }
  }

  // private inner class event handler
  private class ButtonHandler implements EventHandler<ActionEvent>
  {
    @Override
    public void handle( ActionEvent event )
    {
      for ( int i = 0; i < squares.length; i++ )
      {
        for ( int j = 0; j < squares[i].length; j++ )
        {
          if ( event.getSource( ) == squares[i][j] )
          {
            squares[i][j].setText( game.getSquareText( i, j ) );
            return;
          }
        }
      }
    }
  }
}
```

Description

The *BoardView* class, shown in Example 17.28, extends *GridPane*. In this way, we can set a *BoardView* object as the root of the scene that we place on the stage.

A two-dimensional array of *Buttons*, named *squares* (line 13), makes up the chessboard. We declare an instance variable of type *BoardGame,* our Model, at line 12. The constructor (lines 15–57) defines the GUI and sets up event handling. We call the constructor of *GridPane* at line 17 and retrieve the number of rows and columns from the Model at lines 20 through 22. At lines 23 through 30, we define and add row and column constraints. After instantiating a *RowConstraints* object at line 23, we set its percentage height to 100%, divided by the number of rows. We then add that row constraint to the list of row constraints as many times as there are rows (lines 27–28). In this way, each row has the same height. We define the column constraints similarly, so that each column has the same width.

At line 33, we declare and instantiate the listener *bh*, a *ButtonHandler* object reference. Because we are interested in events related to buttons, our *ButtonHandler private* inner class implements the *EventHandler* interface and overrides the *handle* method. At line 32, we instantiate the two-dimensional array *squares*. We have a two-dimensional array of *Buttons*, so we use nested *for* loops at lines 35 through 56 to instantiate the *Buttons*, add them to the *GridPane*, and register the listener on all the buttons. Using FXML, to include a *Button* in a layout container, we define a *Button* element and specify attributes for that *Button* element in an *.fxml* file. To create and define a *Button* programmatically, we instantiate the *Button* using a constructor and call various methods to set its properties. These setter methods typically accept a parameter that represents the new value for the *Button* property. Some of these methods are shown in **Table 17.28**. Remember from Figure 17.2 that the *Button* class is a subclass of *ButtonBase*, *Labeled*, *Control*, *Region*, *Parent*, *Node*, and *Object*, and inherits some properties from its superclasses.

Selected Methods of and Inherited by the *Button*

Class

Package	**javafx.scene.control**
Constructor	
`Button( )`	
creates an empty Button	
Return value	**Method name and argument list**
`void`	`setStyle( String style )`
sets the value of the *style* property of this *Button* to *style*, which is expected to be a CSS-like *String*. This method is inherited from *Node*.	
`void`	`setMaxWidth( double value )`
sets the value of the *maxWidth* property of this *Button* to *value*. This method is inherited from *Region*.	
`void`	`setMaxHeight( double value )`
sets the value of the *maxHeight* property of this *Button* to *value*. This method is inherited from *Region*.	
`void`	`setOnAction( EventHandler<ActionEvent> handler )`
registers *handler* as the event handler for this *Button*. When the button is clicked, the *handle* method of handler's class will be called automatically. This method is inherited from *ButtonBase*.	

Description

At lines 42 through 44, we color the squares according to the coloring pattern and colors set in the Model. In order to do this, we call the *setStyle* method of the *Button* class, inherited from *Node*, and also shown in Table 17.28. The *setStyle* method accepts a CSS-like *String* parameter composed of a semicolon-separated list of attribute-value pairs, with each attribute and value separated by a colon (:). The format of the CSS-style *String* parameter is as follows:

```
"styleAttribute1:value1;styleAttribute2:value2;styleAttribute3:value3; ..."
```

Description

For example, if we want to set the background color to blue and the text's font size to 25, we could use the following *String* as the parameter to the *setStyle* method:

```
"-fx-background-color:blue;-fx-font-size:25"
```

Description

At lines 49 through 51, we ensure that each *Button* will fill the available space within the *GridPane* by setting its maximum width and height to the maximum possible value by calling the *setMaxWidth* and *setMaxHeight* methods (see Table 17.28), using the *static* constant of the *Double* wrapper class (*Double.MAX_VALUE*) that represents the maximum value that a *double* data type can hold. If we remove these statements, the *Buttons* will be sized to their default size, which is based on their contents: in this case, the button's text and the font size of that text. At lines 53 and 54, we call the *setOnAction* method (see Table 17.28) to register the *ButtonHandler bh* on each *Button*.

REFERENCE POINT

For a complete listing of JavaFX style attributes, see *https://docs.oracle.com/javafx/2/api/javafx/scene/doc-files/cssref.html*.

In the *handle* method, we use nested *for* loops at lines 65 through 75 to identify the source of the event, that is, which button the user clicked. We then set the text of that button to its board position (line 71), retrieving the corresponding value from the Model. Having found the source of the event, we then exit the event handler via the *return* statement (line 72) to interrupt the *for* loops and thus avoid unnecessary processing.

Finally, the *ChessBoard* class, shown in **Example 17.29**, includes the *main* and *start* methods to create a *BoardView* showing a *BoardGame* game. The *letters*, *digits*, and *boardColors* arrays (lines 14–16) define the board. Try changing either the *letters*, *digits*, or *boardColors* array and running the application again. The grid will be resized correctly and with new colors, showing the reusability of our classes.

Example 17.29 The *ChessBoard* Class

```
/*  ChessBoard class
    Anderson, Franceschi
*/

import javafx.application.Application;
import javafx.scene.paint.Color;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class ChessBoard extends Application
{
  public void start( Stage stage )
  {
    char [ ] letters = { 'a', 'b', 'c', 'd', 'e', 'f', 'g', 'h' };
    int [ ] digits = { 8, 7, 6, 5, 4, 3, 2, 1 };
    Color [ ] boardColors = { Color.WHITE, Color.RED };

    BoardGame game = new BoardGame( digits, letters, boardColors );
    BoardView view = new BoardView( game );

    Scene scene = new Scene( view, 450, 450 );
    stage.setScene( scene );
    stage.setTitle( "Click a square to reveal its position" );
    stage.show( );
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

Figure 17.13 shows the application if we eliminate the row and column constraints by commenting out lines 23 through 30 of Example 17.28. Similarly, we will have the same result if we comment out lines 49 through 51, because the buttons will have their computed preferred size, which is based on their content. As we see, the cells do not fill up the width and height of the *GridPane*; the buttons have their default minimum size because they are empty. When we click on a button, it expands in width to display its new text, and the width of the whole column increases accordingly.

17.11 Layout Containers: Dynamically Setting Up the GUI Using *GridPane*

Layout managers can be set dynamically, based on user input. For example, the user could enter the number of rows or columns of the grid. Based on user input, we can also rearrange the components using another layout container, such as *HBox*. The user could also instruct us to remove components and add others. Our next example, the Tile Puzzle game, will illustrate some of these capabilities.

In the Tile Puzzle game, eight tiles displaying the digits 1 through 8 are scrambled on a 3-by-3 grid, leaving one cell empty. Any tile adjacent to the empty cell can be moved to the empty cell by clicking on the numbered tile. The goal is to rearrange the tiles so that the numbers are in the correct order, as shown in **Figure 17.14**.

Figure 17.14 The Winning Position of a 3-by-3 Tile Puzzle Game

Description

The Tile Puzzle game can also be played on a 4-by-4, 5-by-5, and more generally, *n*-by-*n* grid. In this example, we set up a 3-by-3 grid for the first game and then randomly select a 3-by-3, 4-by-4, 5-by-5, or 6-by-6 grid for subsequent games. Later, we can modify this example to allow the user to specify the size of the grid.

Before designing the GUI class, we first code the Model, a class to encapsulate the functionality of the tile puzzle game; the *TilePuzzle* class (**Example 17.30**) handles the creation of a game of a given size, enables play, and enforces the rules of the game.

Example 17.30 The *TilePuzzle* Class

```java
/** TilePuzzle class
*   Anderson, Franceschi
*/

public class TilePuzzle
{
 private String [ ][ ] tiles;
 private int side; // grid size
 private int emptyRow;
 private int emptyCol;

 /** constructor
 * @param newSide grid size
 */
 public TilePuzzle( int newSide )
 {
  setUpGame( newSide );
 }

 /** setUpGame
 * @param newSide grid size
 */
 public void setUpGame( int newSide )
 {
  if ( newSide < 3 )
   side = 3;
  else
   side = newSide;
  emptyRow = side - 1;
  emptyCol = side - 1;
  tiles = new String[side][side];

  // initialize tiles
  for ( int i = 0; i < side; i++ )
  {
   for ( int j = 0; j < side; j++ )
   {
    tiles[i][j] = String.valueOf( ( side * side )
                                - ( side * i + j + 1 ) );
   }
  }
  // set empty cell label to blank
  tiles[side - 1][side - 1] = "";
 }

 /** getSide
 * @return side
 */
 public int getSide( )
 {
   return side;
 }

 /** getTiles
 * @return a copy of tiles
 */
 public String[ ][ ] getTiles( )
 {
  String[ ][ ] copyOfTiles = new String[side][side];

  for ( int i = 0; i < side; i++ )
  {
   for ( int j = 0; j < side; j++ )
   {
    copyOfTiles[i][j] = tiles[i][j];
   }
  }
  return copyOfTiles;
 }

 /** tryToPlay
 * enable play if play is legal
 * @return true if the play is legal, false otherwise
 */
 public boolean tryToPlay( int row, int col )
 {
  if ( possibleToPlay( row, col ) )
  {
   // play: switch empty String and tile label at row, col
   tiles[emptyRow][emptyCol] = tiles[row][col];
   tiles[row][col] = "";
   // update emptyRow and emptyCol
   emptyRow = row;
   emptyCol = col;
   return true;
  }
  else
   return false;
 }

 /** possibleToPlay
 * @return true if the play is legal, false otherwise
 */
 public boolean possibleToPlay( int row, int col )
 {
  if ( ( col == emptyCol && Math.abs( row - emptyRow ) == 1 )
         || ( row == emptyRow && Math.abs( col - emptyCol ) == 1 ) )
   return true;
  else
   return false;
 }

 /** won
 * @return true if correct tile order, false otherwise
 */
 public boolean won( )
 {
  for ( int i = 0; i < side ; i++ )
  {
   for ( int j = 0; j < side; j++ )
   {
    if ( !( tiles[i][j].equals(
            String.valueOf( i * side + j + 1 ) ) )
       && ( i != side - 1 || j != side - 1 ) )
       return false;
   }
  }
  return true;
 }
}
```

Description

The instance variable *tiles* (line 7), a two-dimensional array of *Strings*, stores the state of the puzzle. Each element of *tiles* represents a cell in the puzzle grid. The instance variable *side*, declared at line 8, holds the size of the grid. The instance variables *emptyRow* and *emptyCol*, declared at lines 9 and 10, identify the empty cell in the puzzle grid.

The constructor (lines 12–18) calls the *setUpGame* method (lines 20–44), passing the size of the grid (*newSide*) as an argument. The controller also calls the *setUpGame* method before starting each new game.

Inside the *setUpGame* method, we assign *newSide* to *side*. Rather than randomly generating each tile label, which would complicate this example, we assign the labels to the tiles in descending order using nested *for* loops (lines 33–41). We set the empty cell to the last cell in the grid (lines 42 and 43).

The *tryToPlay* method (lines 71–89) first checks if the play is legal by calling the *possibleToPlay* method (line 77). The play is legal if the tile the user clicked is next to the empty tile. If the *possibleToPlay* method returns *true*, we proceed with the play and return *true*; otherwise, we return *false*. Playing means swapping the values of the empty cell (*emptyRow*, *emptyCol*) and the cell that was just played, represented by the two parameters of the *tryToPlay* method, *row* and *col*.

The *possibleToPlay* method is coded at lines 91 through 101. If the play is legal—that is, if the tile played is within one cell of the empty cell—the method returns *true*; otherwise, the method returns *false*.

The *won* method (lines 103–119) checks if the tiles are in order. If so, the *won* method returns *true*; otherwise, the method returns *false*.

As in the chessboard example, when the user clicks on a button, we need to identify the row and the column of that button. In order to avoid looping through all the buttons, we create a class that *extends* the *Button* class and we add two instance variables for the row and column indexes. In this way, when a button belonging to a two-dimensional array of buttons is clicked, we can access its *row* and *column* instance variables in order to identify which button was clicked.

Example 17.31 shows the *GridButton* class, which extends the *Button* class and adds two instance variables, *row* and *column* (lines 9–10). The constructor at lines 12 through 22 allows the client to create a *GridButton* object with a specified text, row, and column. Note that this class is not specific to the tile puzzle application and can be reused for other applications involving an array of buttons placed on a grid.

Example 17.31 The *GridButton* Class

```java
/** GridButton class
*   Anderson, Franceschi
*/

import javafx.scene.control.Button;

public class GridButton extends Button
{
 private int row;
 private int column;

 /** Constructor
 * @param title text for button
 * @param newRow row
 * @param newColumn column
 */
 public GridButton( String title, int newRow, int newColumn
 {
  super( title );
  setRow( newRow );
  setColumn( newColumn );
 }

 /** getRow method, accessor for row
 * @return row
 */
 public int getRow( )
 {
   return row;
 }

 /** getColumn method, accessor for column
 * @return column
 */
 public int getColumn( )
 {
   return column;
 }

 /** setRow method, mutator for row
 * @param row, new value for row
 */
 public void setRow( int row )
 {
   if ( row >= 0 )
     this.row = row;
 }

 /** setColumn method
 * @param column, new value for column
 */
 public void setColumn( int column )
 {
   if ( column >= 0 )
     this.column = column;
 }
}
```

Description

Figure 17.15 shows the UML diagram for the *TilePuzzle* and *TilePuzzleViewController* classes.

Figure 17.15 The UML Diagram for *TilePuzzle* and *TilePuzzleViewController*

Description

Example 17.32 shows the *TilePuzzleViewController* class; as in the *BoardView* class in the previous example, it is a subclass of *GridPane* (line 12) and combines the View and the Controller.

Example 17.32 The *TilePuzzleViewController* Class

```java
/* Using GridPane dynamically
   Anderson, Franceschi
*/

import java.util.Random;
import javafx.event.ActionEvent;
import javafx.event.EventHandler;
import javafx.scene.control.Alert.AlertType;
import javafx.scene.control.*;
import javafx.scene.layout.*;

public class TilePuzzleViewController extends GridPane
{
  private GridButton [ ][ ] squares;
  private TilePuzzle game; // the tile puzzle game

  public TilePuzzleViewController( TilePuzzle newGame )
  {
    super( );
    game = newGame;
    setUpGameGUI( );
  }

  public void setUpGameGUI( )
  {
    // remove all components and constraints
    getChildren( ).clear( );
    getRowConstraints( ).clear( );
    getColumnConstraints( ).clear( );

    // set up grid constraints
    RowConstraints row = new RowConstraints( );
    row.setPercentHeight( 100.0 / game.getSide( ) );
    ColumnConstraints col = new ColumnConstraints( );
    col.setPercentWidth( 100.0 / game.getSide( ) );
    for ( int i = 0; i < game.getSide( ); i++ )
      getRowConstraints( ).add( row );
    for ( int j = 0; j < game.getSide( ); j++ )
      getColumnConstraints( ).addAll( col );

    squares = new GridButton [game.getSide( )][game.getSide( )];
    ButtonHandler bh = new ButtonHandler( );

    for ( int i = 0; i < game.getSide( ); i++ )
    {
      for ( int j = 0; j < game.getSide( ); j++ )
      {
        squares[i][j] = new GridButton( game.getTiles( )[i][j], i, j );

        // add the button
        add( squares[i][j], j, i );

        // make button fill up available width and height
        squares[i][j].setMaxWidth( Double.MAX_VALUE );
        squares[i][j].setMaxHeight( Double.MAX_VALUE );

        // register listener on button
        squares[i][j].setOnAction( bh );
      }
    }
  }

  public void update( )
  {
    for ( int i = 0; i < game.getSide( ); i++ )
      for ( int j = 0; j < game.getSide( ); j++ )
         squares[i][j].setText( game.getTiles( )[i][j] );

    if ( game.won( ) )
    {
      showMessageDialog( "Congratulations",
                         "You won\nSetting up a new game" );
      Random random = new Random( );
      int sideOfPuzzle = 3 + random.nextInt( 4 );
      game.setUpGame( sideOfPuzzle );
      setUpGameGUI( );
    }
  }

  public void showMessageDialog( String title, String message )
  {
    Alert alert = new Alert( AlertType.INFORMATION );
    alert.setTitle( title );
    alert.setHeaderText( "" );
    alert.setContentText( message );
    alert.showAndWait( );
  }

  // private inner class event handler
  private class ButtonHandler implements EventHandler<ActionEvent>
  {
    @Override
    public void handle( ActionEvent event )
    {
      GridButton button = ( GridButton ) event.getSource( );
      if ( game.tryToPlay( button.getRow( ), button.getColumn( ) ) )
        update( );
    }
  }
}
```

Description

Each tile in the game is a *GridButton*. The instance variable *squares* (line 14) holds a two-dimensional array of *GridButtons* so that each element of *squares* is a cell in the game grid. The *TilePuzzle* instance variable *game*, declared at line 15, represents the Model. When the user plays, we call the various methods of the *TilePuzzle* class to enforce the rules of the game.

The constructor (lines 17–22) calls the constructor of *GridPane*, instantiates *game,* and calls the *setUpGameGUI* method. The constructor and the *setUpGameGUI* method define the View. The *private* inner class *ButtonHandler* (lines 90–100) and the *update* method (lines 63–78) make up the Controller.

The *setUpGameGUI* method (lines 24–61) displays the game in its starting position. We first remove all the components and the row and column constraints from this *GridPane* (lines 26–29). In order to access the children of this *GridPane*, we call the *getChildren* method inherited from *Pane* and shown in **Table 17.29**. It returns an *ObservableList* of *Nodes* that are the children of this *GridPane*. With it, we call the *clear* method that *ObservableList* inherits from the *List* interface. That removes all the *Buttons* from this *GridPane*. Because the next game may be 3-by-3, 4-by-4, or 5-by-5 grids, we also need to remove the current row and column constraints of this *GridPane*. We access them using the *getRowConstraints* and *getColumnConstraints* methods of the *GridPane* class, shown earlier in Table 17.24. They also return a list of *Observable* objects, *RowConstraints,* and *ColumnConstraints*, respectively. We remove these constraints by calling the *clear* method, shown in Table 17.25. We then reset the row and column constraints of this *GridPane* layout container at lines 31 through 39. We instantiate the *squares* array and our event handler at lines 41 and 42. After that, we use nested *for* loops (lines 44–60) to instantiate each button, add it to the container, force the button to fill the available width and height, and register the event handler. The *squares* array parallels the *tiles* array of the *TilePuzzle* class; the *squares* buttons are labeled with the values of *tiles*.

The *getChildren* Method of the *GridPane* Class Inherited from the *Pane* Class

Package	**javafx.scene.layout**
Return value	**Method name and argument list**
`ObservableList<Node>`	`getChildren( )`
returns the children of this pane as an *ObservableList* of *Nodes*	

Description

When a button is clicked, our *ButtonHandler handle* method is executed. To determine which button was clicked, we call the *getSource* method using the *ActionEvent* event object that was sent to the method (line 96). Because the *getSource* method returns an *Object*, we need to type cast the return value to a *GridButton*. We then need to determine whether the button clicked was a legal play. To do this, we call the *tryToPlay* method at line 97 with the *row* and *column* instance variable values of the button. If that method returns *true*, the play was legal and the model has changed (i.e., a tile has been moved). We then call the *update* method to make the view (i.e., the buttons) reflect the model (line 98).

The *update* method first updates the *squares* button array (lines 65–67). We then test if the current move solved the puzzle by calling the *won* method (line 69) of the *TilePuzzle* class. If the *won* method returns *true*, we congratulate the user by popping up a dialog box at lines 71 and 72.

The *Alert* class, part of the *javafx.scene.control* package, enables us to display one of many predefined dialog boxes. A constructor and several methods are shown in **Table 17.30**. Most methods of *Alert* are inherited from its superclass, *Dialog*. The constructor accepts an *Alert.AlertType* parameter that defines the type of dialog box that we want to display. *Alert.AlertType*, a *static* inner class of *Alert*, is an *enum* that defines several constants that can be used to configure the icon and style of the dialog box. The *INFORMATION* type is used to configure the dialog box so that it just informs the user of something. Other types are CONFIRMATION, ERROR, WARNING, and NONE. At line 82 of the *showMessageDialog* method (lines 80–87), we instantiate a dialog box using the *INFORMATION* type. We then set the contents of the dialog box at lines 83–85. Note that if we did not set the header text of the dialog box to an empty *String* at line 84, the dialog box would be bigger and look a bit awkward. Finally, we display the dialog box at line 86 by calling the *showAndWait* method.

Constructor and Useful Methods of the *Alert* Class

Package	**javafx.scene.control**
Constructor	
`Alert( Alert.AlertType type )`	
constructs an *Alert* of type *type*.	
Return value	**Method name and argument list**
`void`	`setTitle( String title )`
sets the title of this dialog box.	
`void`	`setHeaderText( String message )`
sets the text to display in the header of this dialog box. If *message* is the empty *String*, no space is allocated for the header and the dialog box will be smaller.	
`void`	`setContentText( String message )`
sets the text to display inside dialog box.	
`Optional<R>`	`showAndWait( )`
shows this dialog box and waits for the user's response.	

Description

We then randomly generate a grid size between three and six (lines 73–74) for the next game and call the *setUpGame* method (line 75) and the *setUpGameGUI* method (line 76) to begin a new game with the new grid size.

Finally, the *PlayTilePuzzle* class, shown in **Example 17.33**, includes the *main* and *start* methods to create a *TilePuzzleViewController* application showing a *TilePuzzle* game. **Figure 17.16** shows a run of this game after the user has moved some tiles.

Example 17.33 The *PlayTilePuzzle* Class

```
/*  PlayTilePuzzle class
    Anderson, Franceschi
*/

import javafx.application.Application;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class PlayTilePuzzle extends Application
{

  @Override
  public void start( Stage stage )
  {
    TilePuzzle puzzle= new TilePuzzle( 3 );
    TilePuzzleViewController root
      = new TilePuzzleViewController( puzzle );

    Scene scene = new Scene( root, 350, 350 );
    stage.setTitle( "The tile puzzle game" );
    stage.setScene( scene );
    stage.show( );
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

17.12 *BorderPane* Layout, Animations, Sounds, and Lambda Expressions

We have a lot to talk about in this section. We introduce a new layout class, *BorderPane*. We demonstrate animating nodes with some accompanying sound. And we explain using lambda expressions for event handlers.

A *BorderPane* layout container organizes its nodes into five positions: *top*, *bottom*, *left*, *right*, and *center*, with each position holding, at most, one node. The size of each position expands or contracts depending on the size of the node in that position, the sizes of the nodes in the other positions, and whether the other positions contain a node. The *center* position expands to fill any remaining space; if not enough space is allocated, some positions may overlap other positions. Thus, for each position, we can add zero or one node. In contrast to the previously discussed layout containers, we can define the positions and nodes for a *BorderPane* in any order. **Figure 17.17** shows the five possible positions in a *BorderPane* layout.

Figure 17.17 The Five Positions of the *BorderPane* Layout

Description

To illustrate the *BorderPane* layout, we will write an application that animates a Sprite defined in **Example 17.34**. We've made some changes to the *Sprite* class. Because we want to animate the Sprite, we define the class as extending the *Canvas* class. The default constructor (lines 15–22) calls the constructor of the *Canvas* class, setting the width and height of the canvas to be the width and height of the Sprite. The overloaded constructor is similar (lines 24–35), except that it sets the canvas size to the Sprite's width and height multiplied by the validated *scale*. **Figure 17.18** shows the window when the *AnimationSampler* application begins, and **Example 17.35** shows the FXML file we use to define the layout and nodes.

Example 17.34 The *Sprite.java* File

```java
/* Sprite class
   Anderson, Franceschi
*/
import javafx.scene.canvas.*;
import javafx.scene.paint.*;

public class Sprite extends Canvas
{

17     <Button text="Scale" fx:id="scaleButton" />
18     <Button text="Combine Animations" fx:id="combineButton" />
19     <Button text="Start Translate" fx:id="startTranslateButton" />
20     <Button text="Stop Translate" fx:id="stopTranslateButton" />
21   </VBox>
22  </left>
23 </BorderPane>
```

Description

In Example 17.35, we define the top-level layout as a *BorderPane* (lines 5–6 and 23). We specify the *BorderPane* positions using FXML elements. In the *center* position, we place an empty *VBox* (lines 7–10). In the controller's *initialize* method, we will add the Sprite to this *VBox* and draw it. In the *left* position, we place the *VBox* containing the buttons (lines 11–22). Because at most one node can be placed into each position, we place multiple nodes into the *VBox* layout and place the *VBox* layout as the single node in the *left* position. We do not define any nodes for the *top*, *right*, or *bottom* positions. Thus, the *left* position is sized to fit the buttons, and the *center* position expands to fill the window. We define navy borders around the *VBoxes* (lines 9 and 13) so we can see their relative sizes and placement.

JavaFX supports two kinds of animations: transitions and timeline animations. Animations vary the properties of nodes, such as the opacity, position, or size, over a specified time period. In timeline animations, we can define custom variations of properties over time. In this chapter, we concentrate on predefined transitions.

Transitions use a technique called **tweening**, which gives the illusion of a property varying “between” two states by creating and displaying a series of intermediate frames over time. We can define individual transitions or combine multiple transitions to be played sequentially or in parallel.

JavaFX’s *abstract Transition* class inherits from the *abstract Animation* class. Each type of transition is a concrete subclass of the *Transition* class. All these classes are in the *javafx.animation* package.

To create an animation, we instantiate an object of the appropriate *Transition* subclass, tie the animation to a node, and specify the beginning and ending states of a property and the time period over which to vary the property. When ready, we play the transition. JavaFX automatically handles the variation of the property over time by creating intermediate frames. By default, the property varies from the start state to the end state at a constant rate.

In our *AnimationSampler* application, we demonstrate several kinds of transitions:

- *FadeTransition*, which varies the opacity of a node so that it fades in or out
- *RotateTransition*, which rotates a node a specified number of degrees
- *ScaleTransition*, which varies the size of a node
- *TranslateTransition*, which moves a node by varying its *x* or *y* coordinate, or both
- *SequentialTransition*, which plays a series of transitions one after the other
- *ParallelTransition*, which plays multiple transitions simultaneously

Some methods that all transitions inherit from the *Animation* class are shown in **Table 17.31**. The *setCycleCount* method allows us to specify how many times to run the animation. If we set the *autoReverse* property to *true*, the animation will play in reverse every other cycle. When we call the *play* method, the JavaFX platform manages the playing of the transition. We cannot alter the properties of the transition while it is playing. The only method that affects a running animation is *stop*. The *setOnFinished* method allows us to define an event handler to execute when the animation finishes. In addition, each transition has properties and methods specific to its animation.

Some Methods Common to *Animation* Subclasses

Package	**javafx.animation**
Common Methods of *Animation* Subclasses	
Return value	**Method name and argument list**
`void`	`play( )`
plays the animation from its current position	
`void`	`setAutoReverse( boolean value )`
if *value* is true, animation reverses on alternate cycles; if false, animation repeats from start position on each cycle	
`void`	`setCycleCount( int value )`
sets the animation to execute *value* times; if set to Animation.INDEFINITE, animation will run until stopped	
`void`	`setOnFinished( EventHandler<ActionEvent> handler )`
registers event handler's code to run when the animation finishes	
`void`	`stop( )`
stops the animation, if playing	

Description

We manage all the animations for our application in the controller, shown in **Example 17.36**. In the *initialize* method, we create our Sprite, which is a *Canvas*, and add it to the *VBox* we placed in the *center* position of the *BorderPane* (lines 34–37).

Example 17.36 *AnimationController.java*

```java
  1 /*  Animation Controller
  2     Anderson, Franceschi
  3 */
  4 import java.net.URL;

  6 import javafx.animation.*;
  7 import javafx.event.*;
  8 import javafx.fxml.*;
  9 import javafx.scene.canvas.*;
 10 import javafx.scene.control.*;
 11 import javafx.scene.layout.*;
 12 import javafx.scene.media.AudioClip;
 13 import javafx.util.Duration;
 14 
 15 public class AnimationController
 16 {
 17   @FXML private Button fadeButton, rotateButton,
 18                        scaleButton, combineButton,
 19                        startTranslateButton, stopTranslateButton;
 20   @FXML private VBox canvasContainer;
 21 
 22   private FadeTransition ftFade;
 23   private RotateTransition rtHalf, rtFull;
 24   private TranslateTransition ttStraight, ttDiagonal;
 25   private ScaleTransition stLarger, stSmaller, stSqueeze;
 26   private SequentialTransition sequential;
 27   private ParallelTransition parallel;
 28 
 29   private AudioClip sound;
 30 
 31   @FXML public void initialize( )
 32   {
 33     // Sprite extends Canvas
 34     Sprite sprite = new Sprite( 0, 0, 1 );
 35     GraphicsContext gc = sprite.getGraphicsContext2D( );
 36     sprite.draw( gc );
 37     canvasContainer.getChildren( ).add( sprite );
 38 
 39     // fade for 3 seconds, then reverse
 40     ftFade = new FadeTransition( Duration.seconds( 3 ), sprite );
 41     ftFade.setFromValue( 1.0 );
 42     ftFade.setToValue( 0.1 );
 43     ftFade.setCycleCount( 2 );
 44     ftFade.setAutoReverse( true );
 45     fadeButton.setOnAction( event -> runTransition( ftFade ) );
 46 
 47     // sound effect
 48     URL resource = getClass( ).getResource( "whoosh.m4a" );
 49     sound = new AudioClip( resource.toString( ) );
 50     sound.setCycleCount( 2 );
 51 
 52     // rotate 180 degrees and back
 53     rtHalf = new RotateTransition( Duration.millis( 3000 ), sprite );
 54     rtHalf.setFromAngle( 0 );
 55     rtHalf.setToAngle( 180 );
 56     rtHalf.setCycleCount( 2 );
 57     rtHalf.setAutoReverse( true );
 58     rotateButton.setOnAction( event ->
 59                               {
 60                                 runTransition( rtHalf );
 61                                 sound.play( );
 62                               }
 63                             );
 64 
 65     // reduce size to 1/2, return to start size
 66     stSmaller = new ScaleTransition( Duration.millis( 1500 ), sprite );
 67     stSmaller.setToX( 0.5f );
 68     stSmaller.setToY( 0.5f );
 69     stSmaller.setCycleCount( 2 );
 70     stSmaller.setAutoReverse( true );
 71 
 72     // reduce x size to 1/2, return to start size
 73     stSqueeze = new ScaleTransition( Duration.millis( 1500 ), sprite );
 74     stSqueeze.setToX( 0.5f );
 75     stSqueeze.setCycleCount( 2 );
 76     stSqueeze.setAutoReverse( true );
 77 
 78     sequential = new SequentialTransition( stSmaller, stSqueeze );
 79     scaleButton.setOnAction( event -> runTransition( sequential ) );
 80 
 81     // move right 80 pixels, then return to start
 82     ttStraight = new TranslateTransition( Duration.seconds( 3 ), sprite );
 83     ttStraight.setFromX( 0 );
 84     ttStraight.setToX( 80 );
 85     ttStraight.setCycleCount( 2 );
 86     ttStraight.setAutoReverse( true );
 87 
 88     // rotate 360 degrees
 89     rtFull = new RotateTransition( Duration.millis( 3000 ), sprite );
 90     rtFull.setByAngle( 360 );
 91 
 92     // increase size by half, return to start size
 93     stLarger = new ScaleTransition( Duration.millis( 1500 ), sprite );
 94     stLarger.setToX( 1.5f );
 95     stLarger.setToY( 1.5f );
 96     stLarger.setCycleCount( 2 );
 97     stLarger.setAutoReverse( true );
 98 
 99     parallel = new ParallelTransition( ttStraight, rtFull, stLarger );
100     combineButton.setOnAction( event -> runTransition( parallel ) );
101 
102     // move diagonally up 100 pixels, then return to start
103     ttDiagonal = new TranslateTransition( Duration.millis( 1500 ), sprite );
104     ttDiagonal.setFromX( 0 );
105     ttDiagonal.setToX( 100 );
106     ttDiagonal.setFromY( 0 );
107     ttDiagonal.setToY( -100 );
108     ttDiagonal.setCycleCount( Animation.INDEFINITE );
109     ttDiagonal.setAutoReverse( true );
110     stopTranslateButton.setDisable( true );
111     startTranslateButton.setOnAction( event ->
112                  {
113                     stopTranslateButton.setDisable( false );
114                     runTransition( ttDiagonal );
115                   } );
116 
117     stopTranslateButton.setOnAction( event ->
118                  {
119                     stopTranslateButton.setDisable( true );
120                     ttDiagonal.stop( );
121                     disableButtons( false );
122                   } );
123   }
124 
125   /**
126   *   runTransition
127   *   @param t, the transition to run
128   *   disables buttons, sets animation finished event handler
129   *   plays the animation
130   */
131   public void runTransition( Transition t )
132   {
133      disableButtons( true );
134      t.setOnFinished( event -> disableButtons( false ) );
135      t.play( );
136   }
137 
138   /** disableButtons
139   *   @param mode   true to disable, false to enable
140   */
141   public void disableButtons( boolean mode )
142   {
143      fadeButton.setDisable( mode );
144      startTranslateButton.setDisable( mode );
145      rotateButton.setDisable( mode );
146      scaleButton.setDisable( mode );
147      combineButton.setDisable( mode );
148   }
149 }
```

Description

In the *initialize* method, we define the animations, but we play them only in response to the user pressing a button. Our first transition is a *FadeTransition* that will fade the Sprite out, then in. A constructor for this transition and several useful methods are shown in **Table 17.32**.

A Constructor and Methods of the *FadeTransition* Class

Package	**javafx.animation**
A *FadeTransition* Constructor	
`FadeTransition( Duration time, Node node )`	
creates a *FadeTransition* that will animate *node* for a duration of *time*	
Selected Methods of the *FadeTransition* Class	
Return value	**Method name and argument list**
`void`	`setFromValue( double opacity )`
sets the beginning opacity of the animation; the *opacity* can range from 1.0 (fully opaque) to 0.0 (fully transparent)	
`void`	`setToValue( double opacity )`
sets the ending opacity of the animation; the *opacity* can range from 1.0 (fully opaque) to 0.0 (fully transparent)	

Description

At line 40, we instantiate our *FadeTransition* object. The first argument to the constructor is the length of time the animation should run, specified as a *Duration* object. The *Duration* class (in the *java.util* package) supplies several *static* factory methods to create *Duration* objects in units of milliseconds, seconds, minutes, or hours. These methods are shown in **Table 17.33**. Here we use the *static* factory method *seconds* to specify the length of the animation to be 3 seconds. The second argument of the constructor is the node we are animating, which is the Sprite we created.

Several *static* Factory Methods of the *Duration* Class

Package	**java.util**
Selected *static* Factory Methods of the *Duration* Class	
Return value	**Method name and argument list**
`Duration`	`millis( double ms )`
creates a *Duration* object for *ms* milliseconds	
`Duration`	`seconds( double secs )`
creates a *Duration* object for *secs* seconds	
`Duration`	`minutes( double mins )`
creates a *Duration* object for *mins* minutes	
`Duration`	`hours( double hrs )`
creates a *Duration* object for *hrs* hours	

Description

At lines 41–44, we define the properties of the transition. We set the opacity to vary from fully opaque (1.0) to almost transparent (0.1). We then set the cycle count to 2 so that the animation will repeat once. And we set *autoReverse* to *true* so that on the repeat cycle, the animation will reverse and the opacity will vary from almost transparent to fully visible. The result is that when this transition plays, the Sprite will appear to fade out for 3 seconds, then fade in for 3 seconds.

For running all our animations, we define a method, *runTransition* (lines 125–136), that accepts as a parameter the transition to play. This method calls the *disableButtons* method defined on lines 138–148 so that the user cannot attempt to start another transition while the current transition is running. The method then registers an *onFinished* event handler that re-enables the buttons when the transition ends, and then plays the transition.

Line 134 registers the *onFinished* event handler using a **lambda expression**.

In the examples in this chapter so far, we have defined event handlers in two ways: as *protected* methods that are referenced in the FXML file as the *onAction* property for a node, and as *private* inner classes in the controller. When an event handler is dedicated to only one control, a third option is to define the event handler as an **anonymous class**, that is, a class that we define inline without giving the class a name. Using this option, we can define and register the event handler at the same time. Let's explore this option with the event handler for the *onFinished* event handler. The only action for our event handler is to call the *disableButtons* method to enable the buttons when the animation finishes.

We can register our event handler using the *setOnFinished* method of the *Transition* class (inherited from the *Animation* class). To do this, we define a class that implements the *EventHandler<ActionEvent>* interface. To implement this class, we need to define one method, *handle*, shown in **Table 17.34**.

The *handle* Method of the *EventHandler<T extends Event>* Interface

Package	**javafx.event**
Return value	**Method name and argument list**
`void`	`handle( T event )`
provides code to run when *event* occurs on a registered control	

Description

In the *runTransition* method, we could register and define our event handler as an anonymous class that implements the

EventHandler interface using this code:

```
t.setOnFinished( new EventHandler<ActionEvent>( )
                  {
                     @Override
      public void handle( ActionEvent event )
      {
        disableButtons( false );
      }
   }
);
```

Description

Thus, the argument we send to the *setOnFinished* method is an object reference of the class that implements the *EventHandler<ActionEvent>* interface. We instantiate the object using *new* and define the class by providing the body of the *handle* method inline. Although this code is compact, misplacing a curly brace, parenthesis, or semicolon can generate errors that are difficult to debug. To write this code in a more readable form, we can use lambda expressions, introduced in Java Version 8.

Lambda expressions can be used only with **functional interfaces**, which are interfaces that have only one *abstract* method that the class implementing that interface must define. Thus, the *EventHandler* interface is a functional interface.

A lambda expression contains the following elements:

- A comma-separated list of parameters enclosed in parentheses. The data types of the parameters may be omitted. The parentheses may also be omitted if there is only one parameter.
- The arrow token, ->
- A method body, which can be a single expression or a block enclosed in curly braces
    - If the body of the method consists of a single expression, then the JVM evaluates the expression and returns its value. As an alternative, we can use a *return* statement, but that requires curly braces.

Given this syntax for lambda expressions, we can replace the code above with this single statement:

```
t.setOnFinished( event -> disableButtons( false ) );
```

In fact, this is line 134 in Example 17.36. When the animation finishes, we execute the *disableButtons* method to re-enable the buttons.

We have another opportunity to use lambda expressions in our button handlers. For example, we want the *FadeTransition* to play when the user presses the “Fade” button. This is the only action we want to register for the “Fade” button, and the *setOnAction* method takes an *EventHandler* object, so we are also able to set up an event handler for the button using a lambda expression. Following the syntax explained above, creating and registering the event handler for the “Fade” button is accomplished on line 45. The event handler calls the *runTransition* method passing the name of our *FadeTransition (ftFade)* as an argument.

We gain several advantages by using lambda expressions. The code is even more compact than defining an anonymous class; the code is more readable; and, by defining a separate event handler for each button, we avoid calling the *getSource* method from the event handler to determine which button the user clicked.

Our next animation is a *RotateTransition* that rotates the Sprite 180 degrees clockwise, then reverses to its original orientation while playing a sound effect.

The *AudioClip* class, in the *javafx.scene.media* package, is useful for playing short sounds, such as sound effects. When an *AudioClip* object is instantiated, the sound file is loaded entirely into memory. Thus, this class is intended for playing relatively short sounds. For longer sounds, we would use the *Media* class. You can read more about the *Media* class on Oracle’s Java website.

Table 17.35 shows the constructor and the *play* and *stop* methods of the *AudioClip* class. The constructor accepts a *String* representing a URL for the sound. In this case, we use a locally stored sound, although we could load a sound from the Internet.

A Constructor and Selected Methods of the *AudioClip* Class

Package	**javafx.scene.media**
***AudioClip* Constructor**	
`AudioClip( String source )`	
loads an audio clip from the URL represented by *source*	
Selected Methods of the *AudioClip* Class	
Return value	**Method name and argument list**
`void`	`setCycleCount( int count )`
count is the number of times to play the sound	
`void`	`play( )`
plays the sound	
`void`	`stop( )`
stops the sound, if playing	

Description

In addition to the methods shown in Table 17.35, the *AudioClip* class also provides methods for setting the rate and volume at which the sound is played and other properties. Like animations, we need to set all the properties of the sound before calling the *play* method. Once a sound is playing, the only method that affects it is *stop*.

At line 48, we instantiate a *URL* object for our sound file, *whoosh.m4a*. On line 49, we instantiate the *AudioClip* object. Because the *AudioClip* constructor accepts a *String* argument, we need to call the *toString* method on the *URL* object. We set the cycle count to 2 at line 50 so that the sound will play twice.

Now we're ready to set up the rotation animation. A constructor for the *RotateTransition* class and several useful methods are shown in **Table 17.36**. When calling those methods, we specify angle values in degrees.

A Constructor and Methods of the *RotateTransition* Class

Package	**javafx.animation**
A *RotateTransition* Constructor	
RotateTransition(Duration time, Node node)	
creates a *RotateTransition* that will animate *node* for a duration of *time*	
Selected Methods of the *RotateTransition* Class	
Return value	**Method name and argument list**
`void`	`setFromAngle( double startAngle )`
sets the angle from which to begin the rotation	
`void`	`setToAngle( double endAngle )`
sets the angle at which to end the rotation	
`void`	`setByAngle( double angle )`
sets the angle relative to the start at which to stop	

Description

On lines 52–57, we instantiate the transition and set the rotation for 180 degrees, to repeat in reverse.

When the user presses the *Rotate* button, we want both to start the animation and to play the sound. That means that our event handler (lines 58–63) consists of more than one statement, so, using a lambda expression, we need to place the two statements inside curly braces. Otherwise, the syntax is the same as for the fade animation.

Our next animation is actually two animations that we play sequentially. Using *ScaleTransitions*, we decrease, then "squeeze" the size of the Sprite. A constructor for the

ScaleTransition class and several useful methods are shown in **Table 17.37**. When calling those methods, we specify relative, not absolute, values.

A Constructor and Methods of the *ScaleTransition* Class

Package	**javafx.animation**
A *ScaleTransition* Constructor	
`ScaleTransition( Duration time, Node node )`	
creates a *ScaleTransition* that will animate *node* for a duration of *time*	
Selected Methods of the *ScaleTransition* Class	
Return value	**Method name and argument list**
`void`	`setToX( double value )`
sets the x scale at which to stop	
`void`	`setToY( double value )`
sets the y scale at which to stop	

Description

At lines 65–70, we instantiate a *ScaleTransition* and decrease the size of the Sprite by setting its *x* and *y* scales to 50%. The *x* scale determines how large the node is horizontally, and the *y* scale determines how large the node is vertically. At lines 72–76, we create another *ScaleTransition* that decreases only the *x* scale by 50%. Because we are not changing the *y* scale, when this animation plays, the Sprite appears to be squeezed horizontally.

We want to play these two animations one after the other, so we create a *SequentialTransition* and add both animations as children (line 78). The *SequentialTransition* constructor shown in **Table 17.38** accepts children as a *varargs* argument, so we can add as many animations as desired. When the user presses the “Scale” button, we start the *SequentialTransition* (line 79), which plays the *stSmaller* animation to completion, then automatically plays the *stSqueeze* animation.

A Constructor of the *SequentialTransition* Class

Package	**javafx.animation**
`SequentialTransition( Animation… children )`	
creates a *SequentialTransition* that will play all *children* animations in sequence	

Description

Another way to combine animations is to define a *ParallelTransition*, which plays multiple animations simultaneously. For this, we create three animations: moving the Sprite horizontally, rotating the Sprite, and changing its scale.

To move the Sprite horizontally, we define a *TranslateTransition*, which allows us to change the *x* or *y* coordinate of a node. A constructor for the *TranslateTransition* class and several useful methods are shown in **Table 17.39**.

A Constructor and Methods of the *TranslateTransition* Class

Package	**javafx.animation**
A *TranslateTransition* Constructor	
`TranslateTransition( Duration time, Node node )`	
creates a *TranslateTransition* that will animate *node* for a duration of	

time

Selected Methods of the *TranslateTransition* Class

Return value	Method name and argument list
`void`	`setFromX( double value )`
sets the starting x value	
`void`	`setToX( double value )`
sets the ending x value	
`void`	`setFromY( double value )`
sets the starting y value	
`void`	`setToY( double value )`
sets the ending y value	

Description

We define the *TranslateTransition* at lines 81–86. We move the Sprite right by increasing the *x* coordinate by 80 pixels. Then, because we have two cycles and we have set *autoReverse* to *true*, the Sprite returns to its starting position.

We define the second animation in our set to rotate the Sprite 360 degrees (lines 88–90). We do not set a cycle count or *autoReverse*, so these properties default to one cycle and no *autoReverse*. As a result, the animation will run once.

Our final animation in this set scales the Sprite to 1.5 times and then back to the original size (lines 92–97).

Using the constructor in **Table 17.40**, we now create a *ParallelTransition*, adding our three animations (line 99). When the user presses the “Combine Animations” button, we set the listener to play the parallel animation (line 100), which starts all three animations simultaneously. Notice that not all animations in the set need to have the same duration. For the first 1.5 seconds, the Sprite rotates 180 degrees, moves right 40 pixels, and scales to 1.5 times its size. For the next 1.5 seconds, the Sprite completes its move right, rotates the remaining 180 degrees, and scales back to its original size. For the last 3 seconds, the Sprite moves left to its starting position.

A Constructor of the *ParallelTransition* Class

Package	**javafx.animation**

`ParallelTransition( Animation… children )`

creates a *ParallelTransition* that will play all *children* animations simultaneously

---

Description

For the final animation, we define a *TranslateTransition* that alters both the *x* and *y* values so that the Sprite moves diagonally up to the right (lines 104–111). Note that we set a cycle count of *Animation.INDEFINITE*, which specifies that the animation should keep running until the *stop* method is called. When the user presses the “Start Translate” button, we start the animation, and when the user presses the “Stop Translate” button, we stop the animation. Because the “Stop Translate” button should be enabled only while the animation is running, we set its initial state as disabled (line 110). In the event handler for the “Start Translate” button, we enable the “Stop Translate” button, then start the animation (lines 111–115). In the event handler for the “Stop Translate” button, we disable the “Stop Translate” button, call the *stop* method, then re-enable the rest of the buttons (lines 117–122).

As an animation plays, a **play head** keeps track of the current frame. When we call the *stop* method, the animation stops playing, and its play head is reset to the beginning of the animation. The node, however, remains in the state at which it was stopped. When we again press the “Start Translate” button, we see that because the play head has been reset, the Sprite returns to the start position before beginning the animation.

Example 17.37 shows the *AnimationSampler* code that launches the application.

Example 17.37 *AnimationSampler.java*

```
/*  Animation Sampler
    demonstrates various animations
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.*;
import javafx.fxml.*;
import javafx.scene.layout.*;
import javafx.scene.*;
import javafx.stage.*;

public class AnimationSampler extends Application
{
  @Override
  public void start( Stage stage ) // throws Exception
  {
    try
    {
      URL url =
         getClass( ).getResource( "fxml_animation.fxml" );
      BorderPane root = FXMLLoader.load( url );
      Scene scene = new Scene( root, 800, 600 );
      stage.setTitle( "Animation Sampler" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

17.13 Nesting Components

Components can be nested. Indeed, because the layout containers are subclasses of *Parent*, itself a subclass of *Node*, layout containers are both containers and components. As such, they can contain other layout containers, which in turn can contain components. We can use this feature to achieve more precise layouts.

When nesting components, we usually place several components into a layout container and place that layout container into another layout container. Each layout container can be different so that components can be arranged in many ways. We can even have multiple levels of nesting, as needed.

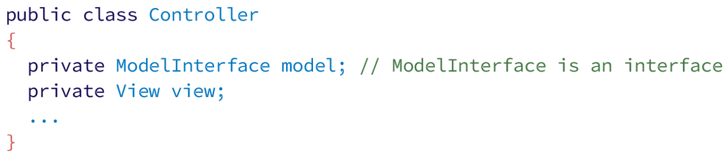
We illustrate nesting of components in an example where, using three colors (red, green, and blue), we randomly generate an 8-by-8 grid of colors. The user tries to guess the most frequently occurring color by clicking on one of the buttons.

Figure 17.19A shows our window when the application begins, and **Figure 17.19B** shows the underlying layout of the window. We use a *BorderPan*e overall, with a *VBox* containing the three buttons on the left side of the *BorderPane*, and a *GridPane* with eight rows and eight columns containing the 64 colored labels in the center position of the *BorderPane*; thus, the two positions we are using, left and center, adjust to fill the space.

Figure 17.19 (A) The Color Frequency Game (B) The Underlying Nested Layout

Description

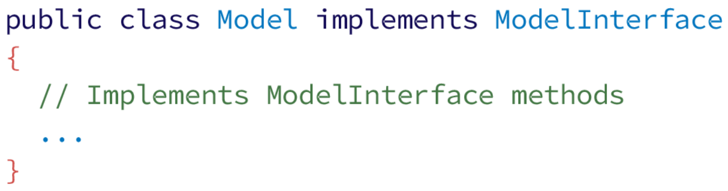
Again, we use the MVC architecture and design our classes for reusability. This time, we also code the Controller so that it is reusable under certain conditions. Inside the *Controller* class, instead of using a class for the Model, we use an interface. Thus, the Controller is now reusable, along with the same View, with any Model that implements that interface. Note that we could also make the View an interface, but in order to keep this example relatively simple, we do not. To achieve reusability for the Controller, we use the following pattern for the *Controller* class:



```
public class Controller
{
  private ModelInterface model; // ModelInterface is an interface
  private View view;
  ...
}
```

Description

The *ModelInterface* specifies several methods to be implemented that the Controller will call to manage the game. The *Model* class uses this pattern:



```
public class Model implements ModelInterface
{
  // Implements ModelInterface methods
  ...
}
```

Description

We want the *Controlle*r class to be reusable with any class whose functionality is based on the user clicking buttons on the left panel with a grid of labels in the center position. We could use this class in an application where the user tries to guess the most frequent color, or the least frequent color, or with a different color system (e.g., HSL—Hue, Saturation, and Lightness).

Thus, we design an interface to support this type of application that has buttons on the left and a grid of labels in the center. **Example 17.38** shows the *ColorGridGame* interface. It specifies methods to retrieve the title for the grid, its size, its number of colors, the label of a color, and the color index of a label. (It is implied that the colors used in the grid of colors will come from an array of colors, and that there will be an array of *Strings* [labels] that parallels that array of colors.) It also specifies methods to test if an answer is the correct answer, as well as to access each color in the grid. We call these methods from the Controller class with the Model instance variable in order to manage the game. The UML diagram for this example is shown in **Figure 17.20**.

Example 17.38 The *ColorGridGame* Interface

```
/* ColorGridGame interface
*  Anderson, Franceschi
*/

import javafx.scene.paint.Color;

public interface ColorGridGame
{
 public String getTitle( );
 public int getSize( );
 public int getNumberOfColors( );
 public String getLabel( int index );
 public int getIndex( String label );
 public boolean isCorrect( int index );
 public String getGridHexColor( int row, int col );
}
```

Description

Figure 17.20 The UML Diagram for the Color Frequency Game Application

Description

We now code our Model for the color frequency game. In this application, we generate colors for our grid of labels. **Example 17.39** shows the *ColorFrequencyGame* class, which *implements ColorGridGame* (line 8). At lines 10 through 12, we declare a *char* array storing hexadecimal digits. We use this array to convert an integer to its hexadecimal equivalent *String*. Its *gridColors* instance variable (line 15) stores a two-dimensional array, or grid, of colors. The *coloringColors* and *counts* arrays (lines 16–17) are parallel arrays: *coloringColors* stores the colors used for coloring the grid, and *counts* stores the frequency of each color. The instance variable *labels* (line 19) is an array of *Strings* that is meant to be labels for the buttons. The *labels* array also parallels the *coloringColors* array.

Example 17.39 The *ColorFrequencyGame* Class

```java
/** ColorFrequencyGame class
    Anderson, Franceschi
*/

import java.util.Random;
import javafx.scene.paint.Color;

public class ColorFrequencyGame implements ColorGridGame
{
 private static char [ ] hexDigits =
    { '0', '1', '2', '3', '4', '5', '6', '7', '8', '9',
      'A', 'B', 'C', 'D', 'E', 'F' };

 private final int DEFAULT_SIZE = 8;
 private Color [ ][ ] gridColors;
 private Color [ ] coloringColors;
 private int [ ] counts; // color frequencies in gridColors

 private String [ ] labels;

 /** Constructor
 * @param size number of rows and columns in gridColors
 * @param colors array of colors
 * @param labels the starting labels
 */
 public ColorFrequencyGame( int size, Color [ ] colors,
                            String [ ] labels )
 {
  if ( size <= 0 )
   size = DEFAULT_SIZE;
  gridColors = new Color[size][size];
  coloringColors = colors;
  counts = new int[coloringColors.length];
  fillGridWithColors( );
  this.labels = labels;
 }

 /** fillGridWithColors method
 * randomly fills gridColors with colors from coloringColors
 */
 public void fillGridWithColors( )
 {
  Random random = new Random( );
  for ( int i = 0; i < gridColors.length; i++ )
  {
   for ( int j = 0; j < gridColors[i].length; j++ )
   {
    int colorIndex = random.nextInt( coloringColors.length );
    gridColors[i][j] = coloringColors[colorIndex];
    counts[colorIndex] += 1;
   }
  }
 }

 /** getSize method
 * @return length of gridColors
 */
 public int getSize( )
 {
  return gridColors.length;
 }

 /** getNumberOfColors method
 * @return length of coloringColors
 */
 public int getNumberOfColors( )
 {
  return coloringColors.length;
 }

 /** getGridHexColor method
 * @param row, an int, the row index
 * @param col, an int, the column index
 * @return a String, the hex equivalent of gridColor[row][col]
 */
 public String getGridHexColor( int row, int col )
 {
  String colorText = "#"
    + toHex( ( int ) ( 255 * gridColors[row][col].getRed( ) ) )
    + toHex( ( int ) ( 255 * gridColors[row][col].getGreen( ) ) )
    + toHex( ( int ) ( 255 * gridColors[row][col].getBlue( ) ) );
  return colorText;
 }

 /** toHex method
 * @return a String, the Hex equivalent of colorIntensity
 */
 public String toHex( int colorIntensity )
 {
  if ( colorIntensity > 255 )
    colorIntensity = 255;
  else if ( colorIntensity < 0 )
    colorIntensity = 0;

  int firstDigit = colorIntensity / 16;
  int secondDigit = colorIntensity % 16;
  return String.valueOf( hexDigits[firstDigit]) + hexDigits[secondDig
 }

 /** highestCount method
 * @return the highest color frequency in the grid
 */
 public int highestCount( )
 {
  int max = counts[0];
  for ( int i = 1; i < counts.length; i++ )
  {
   if ( counts[i] > max )
    max = counts[i];
  }
  return max;
 }

 /** isCorrect method
 * @param index, the index in the coloringColors array to check
 * @return true if the frequency of the color for index
 * is the highest, false otherwise
 */
 public boolean isCorrect( int index )
 {
  return counts[index] == highestCount( );
 }

 /** getTitle method
 * @return a String representing a title for this object
 */
 public String getTitle( )
 {
  return "What is the most frequent color?";
 }

 /** getLabel method
 * @param index, the index of the Color name
 * @return the color name
 */
 public String getLabel( int index )
 {
  return labels[index];
 }

 /** getIndex method
 * @param label, a color name in the labels array
 * @return index of the color name in the labels array
 */
 public int getIndex( String label )
 {
  for ( int i = 0; i < labels.length; i++ )
  {
   if ( labels[i].equals( label ) )
    return i;
  }
  return -1;
 }
}
```

Description

The constructor (lines 21–36) instantiates all three arrays and calls the *fillGridWithColors* method at line 34. The *fillGridWithColors* method (lines 38–53) fills the *colorGrid array* with colors randomly generated from the *coloringColors* array and keeps track of their respective frequency in the *counts* array (line 50).

The *getGridHexColor* method (lines 71–83) returns a hexadecimal representation of the color stored at a specified row and column within the array *gridColors*. It uses the utility method *toHex* (lines 85–98), which converts an integer whose value is between 0 and 255 to its hexadecimal equivalent *String*.

To determine whether the user has chosen the correct color, we provide the *isCorrect* method (lines 114–122), which takes as a parameter the index of the selected color. It returns *true* if the value in *counts* at that index is maximal, *false* otherwise. The *highestCount* method (lines 100–112) calculates and returns the maximum value in the *counts* array. Note that if multiple colors appear with the highest count of labels—essentially a tie—then picking any of those colors will result in a winning selection.

The *getTitle* method (lines 124–130) returns a *String* that can be used as the title of a GUI whose Model is the *ColorFrequencyGame* class. The *getLabel* method (lines 132–139) returns the element of the array *labels* at a specified index, sent as the parameter of the method; that is, the label is to be used with a color located at that index within the array *coloringColors*. The *getIndex* method (lines 141–153) is the opposite method: It returns the index within the array *labels* of a *String*, sent as the parameter of the method; the color corresponding to that label is the element in the array *coloringColors* at that index.

Example 17.40 shows the *BorderedLabelGridView* class. It is a layout container class that *extends BorderPane* (line 16). At its left position, it contains an array of buttons arranged vertically. At its center position, it contains a grid of labels.

Example 17.40 The *BorderedLabelGridView* Class

```java
/** BorderedLabelGridView class
* Reusable generic layout using a BorderPane's
* left and center positions.
* The left VBox is made up of a vertical array of buttons.
* The center position is made up of a grid of labels.
* Accessors are provided so that a Controller can access
* the array of buttons and the 2-dim array (grid) of labels.
* Anderson, Franceschi
*/

import javafx.event.*;
import javafx.scene.control.*;
import javafx.scene.layout.*;
import javafx.scene.paint.Color;

public class BorderedLabelGridView extends BorderPane
{
 private VBox buttonPanel; // left, holds array of buttons
 private Button [ ] buttons;
 private GridPane grid; // center, holds grid of labels
 private Label [ ][ ] labels; // grid of labels

 // numberOfButtons and gridSize must be greater than 0
 public BorderedLabelGridView( int numberOfButtons, int gridSize )
 {
  super( );
  grid = new GridPane( );

  // set up grid as gridSize by gridSize
  RowConstraints row = new RowConstraints( );
  row.setPercentHeight( 100.0 / gridSize );
  ColumnConstraints col = new ColumnConstraints( );
  col.setPercentWidth( 100.0 / gridSize );
  for ( int i = 0; i < gridSize; i++ )
    grid.getRowConstraints( ).add( row );
  for ( int j = 0; j < gridSize; j++ )
    grid.getColumnConstraints( ).addAll( col );

  labels = new Label[gridSize][gridSize];
  for ( int i = 0; i < labels.length; i++ )
  {
   for ( int j = 0; j < labels[i].length; j++ )
   {
    labels[i][j] = new Label( );
    // make label fill up available width and height
    labels[i][j].setMaxWidth( Double.MAX_VALUE );
    labels[i][j].setMaxHeight( Double.MAX_VALUE );
    grid.add( labels[i][j], j, i );
   }
  }

  buttonPanel = new VBox( );

  buttons = new Button[numberOfButtons];
  for ( int i = 0; i < buttons.length; i++ )
  {
   buttons[i] = new Button( );
   // make button fill up available width and height
   buttons[i].setMaxWidth( Double.MAX_VALUE );
   buttons[i].setMaxHeight( Double.MAX_VALUE );
   VBox.setVgrow( buttons[i], Priority.ALWAYS );
   buttonPanel.getChildren( ).add( buttons[i] );
  }

  setLeft( buttonPanel );
  setCenter( grid );
 }

 public void setButtonText( int row, String text )
 {
  buttons[row].setText( text );
 }

 public void setButtonListener( int row, EventHandler<ActionEvent> eh )
 {
  buttons[row].setOnAction( eh );
 }

 public void setLabelBackground( int row, int col, String hexColor )
 {
  labels[row][col].setStyle( "-fx-background-color: " + hexColor );
 }
}
```

Description

Thus, our instance variables are a *VBox* (line 18), which contains an array of *Buttons* (line 19), and a *GridPane* (line 20), which contains a two-dimensional array of *Labels* (line 21). We place the *VBox* in the left position and the *GridPane* in the center position. The other positions within the *BorderPane* are not used.

The constructor (lines 23–67) defines a GUI consisting of an array of buttons on the left, arranged vertically, and a grid of labels in the center, assumed to be a square. Its two parameters represent the number of buttons and the size of the grid. For simplicity, we are not validating these parameters, but both parameters must be greater than 0. The grid of labels is defined at lines 27 through 50 inside the *GridPane*. The array of buttons is defined at lines 52 through 63 inside the *VBox*. At lines 65 and 66, we add the *VBox* and the *GridPane* to this *BorderPane* in the left and center positions, respectively. The *BorderPane* class provides similar methods (*setCenter, setLeft, setRight, setTop,* and *setBottom*) for adding a component to each of its five positions.

We instantiate *grid*, the *GridPane* instance variable, at line 27. At lines 29 through 37, we define row and column constraints so that all the rows in the grid have the same height, all the columns have the same width, and the rows and columns take all the available space in the grid. At lines 39 through 50, we instantiate the labels and add them to the grid, making sure that each label fills the available width and height (lines 45–47).

We instantiate *buttonPanel*, the *VBox* instance variable, at line 52. At lines 54 through 63, we instantiate the buttons and add them to *buttonPanel*, also making sure that each label fills the available width and height (lines 58–61). It is important to set not only the maximum height of the buttons to a high value (line 60), but also their maximum width (line 59). If we do not, the buttons will have uneven width because their text contents are different. It is also important to call the *setVgrow* method (line 61), shown in **Table 17.41**, so that the buttons are expanded vertically in order to fill the available space within the *VBox* to which they belong. The *setVgrow* method sets the priority level for expanding the height of a node that is contained in the *VBox* container. The *setVgrow* method is *static*, so there is no reference to a specific *VBox* when we call this method;

thus, it is assumed that the node is or will be contained in a *VBox*. If we do not call *setVgrow*, the heights of the buttons are not expanded. *Priority* is an *enum* with three possible values: *ALWAYS*, *NEVER*, and *SOMETIMES*. The *ALWAYS* value ensures that the node grows in order to fill the available space in the *VBox* container. We specify the same priority level for all of the buttons so that they grow equally.

The *setVgrow* Method of the *VBox* Class

Package	**javafx.scene.layout**
Return value	**Method name and argument list**
`void`	`setVgrow( Node child, Priority value )`
static method that sets the vertical grow priority of *child*, assuming that *child* is contained in a *VBox*. If set, the *VBox* will allocate additional space for *child* if space is available.	

Description

Finally, we provide methods so that the text of each button and the background color of each label can be set from outside the class (lines 69–72 and 79–82). We also provide a method (lines 74–77) to set an *EventHandler* for each button in the array *buttons*. By calling these methods, the Controller can set up event handling and update this View.

Example 17.41 shows the *ColorGridGameController* class. At lines 13 and 14, we declare our two instance variables: (1) *model*, a *ColorGridGame*; and (2) *view*, a *BorderedLabelGridView*. These instance variables enable us to get user input from the View, call the appropriate methods of the Model, and update the View accordingly.

Example 17.41 The *ColorGridGameController* Class

```java
/** ColorGridGameController class
*   Anderson, Franceschi
*/

import javafx.event.*;
import javafx.scene.control.Alert.AlertType;
import javafx.scene.control.*;
import javafx.scene.layout.*;
import javafx.scene.paint.Color;

public class ColorGridGameController implements EventHandler<ActionEvent>
{
 private ColorGridGame model;
 private BorderedLabelGridView view;

 public ColorGridGameController( ColorGridGame model,
                                 BorderedLabelGridView view )
 {
  this.model = model;
  this.view = view;
  setUpGame( );
 }

 public void setUpGame( )
 {
  setUpLabels( );
  setUpButtons( );
 }

 public void setUpLabels( )
 {
  for ( int i = 0; i < model.getSize( ); i++ )
   for ( int j = 0; j < model.getSize( ); j++ )
    view.setLabelBackground( i, j, model.getGridHexColor( i, j ) );
 }

 public void setUpButtons( )
 {
  for ( int i = 0; i < model.getNumberOfColors( ); i++ )
  {
   view.setButtonText( i, model.getLabel( i ) );
   view.setButtonListener( i, this );
  }
 }

 public void handle( ActionEvent event )
 {
  Button button = ( Button ) event.getSource( );
  int index = model.getIndex( button.getText( ) );

  if ( model.isCorrect( index ) )
      showMessageDialog( "Congratulations", "You won" );
  else
      showMessageDialog( "Sorry", "You lost" );
  // disable buttons here
 }

 public void showMessageDialog( String title, String message )
 {
   Alert alert = new Alert (AlertType.INFORMATION );
   alert.setTitle( title );
   alert.setHeaderText( "" );
   alert.setHeaderText( message );
   alert.showAndWait( );
 }
}
```

Description

The constructor (lines 16–22) accepts two parameters that it assigns to *model* and *view*, and it calls the *setUpGame* method at line 21. The *setUpGame* method (lines 24–28) calls the *setUpLabels* and *setUpButtons* methods.

The *setUpLabels* method (lines 30–35) uses a nested loop to color the grid of labels in the View based on the grid of colors in the Model. At line 34, we set the background color of the current label by calling the View's *setLabelBackground* method, passing the row index, column index, and background color that we retrieve from the Model by calling the *getGridHexColor* method.

The *setUpButtons* method (lines 37–44) places a label on each button in the View based on the label data in the Model and sets up event handling using a single loop. At line 41, we set the text for the current button, passing its index and the label that we retrieve from the Model by calling the *getLabel* method. At line 42, we register *this* object (i.e., this controller, which implements *EventHandler*) on the current button.

We handle the events for the buttons in the *handle* method at lines 46 through 56. We first retrieve the button that originated the event by calling *getSource* at line 48. The *getSource* method returns an *Object*, so we need to type cast the return value to a *Button*. We then retrieve the index of that button's corresponding label by calling the Model's *getIndex* method, passing the text of the button. Next, we check whether the user won or lost by calling the Model's *isCorrect* method, passing that index. Depending on the result, we pop up a dialog box indicating whether the user has won or lost (lines 51–54). The *showMessageDialog* method (lines 58–65) is identical to the one in the puzzle game. After the game is won or lost, we should disable the buttons. This is left as an exercise.

Finally, the *PlayColorCount* class, shown in **Example 17.42**, includes the *main* and *start* methods to create a color count application. We declare an array of three *Colors* at line 16 and a parallel array of *Strings* at line 17, and pass these arrays to the constructor of the *ColorFrequencyGame* at lines 19 through 20. We then create the *BorderedLabelGridView* object *root* at lines 22 and 23. Using *game* and *root*, we create a *ColorGridGameController* at lines 25 and 26. At line 29, we retrieve and set the title of the window. Note that *gam*e "is a*"*

ColorGridGame object because *ColorFrequencyGame* inherits from *ColorGridGame*. **Figure 17.21** shows a run of this example after the user has clicked on the button “GREEN.” To play the game with more colors, we could simply add more colors and labels to the *colors* and *labels* array.

Example 17.42 The *PlayColorCount* Class

```java
/** PlayColorCount class
*   Anderson, Franceschi
*/

import javafx.application.Application;
import javafx.scene.paint.Color;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class PlayColorCount extends Application
{

  @Override
  public void start( Stage stage )
  {
    Color [ ] colors = { Color.RED, Color.GREEN, Color.BLUE };
    String [ ] labels = { "RED", "GREEN", "BLUE" };

    ColorFrequencyGame game
      = new ColorFrequencyGame( 8, colors, labels );

    BorderedLabelGridView root
      = new BorderedLabelGridView( colors.length, game.getSize( ) );

    ColorGridGameController controller
      = new ColorGridGameController( game, root );

    Scene scene = new Scene( root, 450, 425 );
    stage.setTitle( game.getTitle( ) );
    stage.setScene( scene );
    stage.show( );
}

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

17.14 Mouse and Touch Events

A truly interactive application allows the user to point and click using the mouse or to touch the screen. Any mouse activity (clicking, moving, or dragging) by the user generates a *MouseEvent*. Any touch activity by the user generates a *TouchEvent*. When any mouse or touch activity occurs, we will be interested in determining where it happened on the window. To determine the (*x, y*) coordinate of a mouse event, we can call two methods of the *MouseEvent* class, *getSceneX* and *getSceneY*, which are described in **Table 17.42**. To determine the (*x, y*) coordinate of a touch event, we can first call the *getTouchPoint* method of the *TouchEvent* class, which returns a *TouchPoint*, and then call the *getSceneX* and *getSceneY* methods of the *TouchPoint* class. These methods are also shown in Table 17.42.

Useful Classes and Methods for Mouse and Touch Events

Package **javafx.scene.input**

Methods of the *MouseEvent* Class

Return value **Method name and argument list**

`double` `getSceneX( )`

returns the *x* coordinate of this *MouseEvent* in the *Scene* where it occurs

`double` `getSceneY( )`

returns the *y* coordinate of this *MouseEvent* in the *Scene* where it occurs

`double` `getX( )`

returns the x coordinate of the *MouseEvent* relative to the node on which the mouse listener is registered

`double` `getY( )`

returns the y coordinate of the *MouseEvent* relative to the node on which the mouse listener is registered

Method of the *TouchEvent* Class

Return value **Method name and argument list**

`TouchPoint` `getTouchPoint( )`

returns the touch point for this *TouchEvent*

Methods of the *TouchPoint* Class

Return value **Method name and argument list**

`double` `getSceneX( )`

returns the *x* coordinate of this *TouchPoint* in the *Scene* in which it occurs

`double` `getSceneY( )`

returns the *y* coordinate of this *TouchPoint* in the *Scene* in which it occurs

`double` `getX( )`

returns the x coordinate of the *TouchPoint* relative to the node on which the touch listener is registered

`double` `getY( )`

returns the y coordinate of the *TouchPoint* relative to the node on which the touch listener is registered

Description

Our application will implement the *EventHandler* interface. The *EventHandler* interface uses generics. We specify the event type that it uses depending on the type of event that we want to handle. It includes only one method, *handle*, described in **Table 17.43**. Thus, the *EventHandler* interface is a functional interface, and we can use lambda expressions when implementing it.

The *handle* Method of the *EventHandler<T extends Event>* Interface

`void handle( T event )`

This method is called when an event occurs for which this handler is registered.

Description

The *Node* class includes many methods to set up event handling for mouse and touch events, as well as key events. Some of these methods are shown in **Table 17.44**. All the layout container classes, like *VBox* for example, inherit these methods from *Node*. The mouse-related methods accept a parameter of type *EventHandler <? super MouseEvent>*. *EventHandler* is an interface that uses generics. The syntax *<? super MouseEvent>* means that the type of event should be a *MouseEvent* or a superclass of the *MouseEvent* class. Similarly, the event handler for touch events accepts an event that is a *TouchEvent* or a superclass of *TouchEvent*.

Useful Methods of the *Node* Class for Mouse and Touch Events

Methods of the *Node* Class

Return value	Method name and argument

	list
`void`	`setOnMousePressed( EventHandler<? super MouseEvent> handler )`
registers *handler* as the listener to execute when the user presses the mouse. A parameter of *null* removes any previously registered handler.	
`void`	`setOnMouseMoved( EventHandler<? super MouseEvent> handler )`
registers *handler* as the listener to execute when the user moves the mouse. A parameter of *null* removes any previously registered handler.	
`void`	`setOnTouchPressed( EventHandler<? super TouchEvent> handler )`
registers *handler* as the listener to execute when the user touches the screen. A parameter of *null* removes any previously registered handler.	
`void`	`setOnTouchMoved( EventHandler<? super TouchEvent> handler )`
registers *handler* as the listener to execute when the user moves the touch point on the screen. A parameter of *null* removes any previously registered handler.	

Description

To illustrate mouse and touch events, we will build a simple submarine hunt game. A submarine is hidden somewhere in the window, and the user will try to sink the submarine by clicking the mouse or touching the screen at various locations in the window, simulating the dropping of a depth charge. Each time the user clicks the mouse or touches the screen, we will indicate how close that location is to the submarine. If the user's click or touch is too far from the submarine, we will display “In the water” in the title bar and draw a blue circle at the corresponding location. If the user's click or touch is close to the submarine, we will display “Close …” in the title bar. Finally, if the submarine is hit, we will change the title bar to “Sunk!”, display the submarine, and remove the listeners so the game ends.

Figure 17.22 shows the UML diagram for this application. We first code our Model, the *SubHunt* class (**Example 17.43**). It encapsulates the submarine hunt game and enables us to create a game of a given size, enable play, and enforce the rules of the game.

Figure 17.22 UML Diagram for the Sub Hunt Game

Description

Example 17.43 The *SubHunt* Class

```java
/* SubHunt class
*  Anderson, Franceschi
*/

import javafx.scene.canvas.GraphicsContext;
import javafx.scene.paint.Color;
import java.util.Random;

public class SubHunt
{
  public static int DEFAULT_GAME_SIZE = 300;
  public static int SIDE = 36; // size of submarine

  private int gameSize;
  private int xCtr; // x coordinate of center of submarine
  private int yCtr; // y coordinate of center of submarine
  private String status = "";
  private boolean hit;

  /** Constructor
  * @param gameSize the game size
  */
  public SubHunt( int gameSize )
  {
    if ( gameSize > SIDE )
       this.gameSize = gameSize;
    else
       this.gameSize = DEFAULT_GAME_SIZE;
    // generate submarine center
    Random random = new Random( );
    xCtr = SIDE / 2 + random.nextInt( this.gameSize - SIDE );
    yCtr = SIDE / 2 + random.nextInt( this.gameSize - SIDE );
    hit = false;
  }

  /** getStatus Accessor
  * @return status
  */
  public String getStatus( )
  {
    return status;
  }

  /** getGameSize Accessor
  * @return gameSize
  */
  public int getGameSize( )
  {
    return gameSize;
  }

  /** isHit method
  * @return hit, which indicates whether the sub has been hit
  */
  public boolean isHit( )
  {
    return hit;
  }

  /** play method
  * @param x the x coordinate of the play
  * @param y the y coordinate of the play
  */
  public void play( int x, int y )
  {
    // is click within the submarine?
    if ( Math.abs( x - xCtr ) < SIDE / 2
         && Math.abs( y - yCtr ) < SIDE / 2 )
    {
      status = "Sunk!";
      hit = true;
    }
    // is click close?
    else if ( Math.abs( x - xCtr ) < 2 * SIDE
              && Math.abs( y - yCtr ) < 2 * SIDE )
      status = "Close ...";
    // click is too far from submarine
    else
      status = "In the water";
  }

  /** draw method
  * @param gc a GraphicsContext object
  * @param x the x coordinate of the play
  * @param y the y coordinate of the play
  */
  public void draw( GraphicsContext gc, int x, int y )
  {
    if ( status.equals( "Sunk!" ) )
    {
      // draw sunken submarine
      gc.setFill( Color.BLACK );
      gc.fillRoundRect( xCtr - SIDE/2, yCtr - SIDE/2,
                        SIDE/2, SIDE, SIDE/2, SIDE/2 );

      gc.fillRoundRect( xCtr - SIDE/4, yCtr - SIDE/3,
                        SIDE/2, SIDE/2, SIDE/4, SIDE/4 );

      gc.strokeLine( xCtr + SIDE/4, yCtr - SIDE/9,
                     xCtr + SIDE/2, yCtr - SIDE/9 );

      // draw red depth charge
      gc.setFill( Color.RED );
      gc.fillOval( x - SIDE/2, y - SIDE/2, SIDE, SIDE );
    }
    else if ( status.equals( "In the water" ) ) // draw blue circle
    {
      gc.setFill( Color.BLUE );
      gc.fillOval( x - SIDE/2, y - SIDE/2, SIDE, SIDE );
    }
    // else Close ... , do not draw
  }
}
```

Description

Example 17.44 shows the *SubHuntViewController* class, which extends *VBox* (line 11). It combines the View and the Controller. At lines 13–15, we declare our instance variables. The *SubHunt* instance variable *sub* (line 13) represents the Model, the submarine hunt game that we display inside the window. At line 14, we include the instance variable *stage*, a reference to the *Stage*. We use *stage* to call the *setTitle* method (line 64) to update the title of the window each time the user plays. In the next example, we will show how to retrieve a reference to the *Stage* from the Controller class.

Example 17.44 The *SubHuntViewController* Class

```java
/* SubHuntViewController class
*  Anderson, Franceschi
*/

import javafx.scene.layout.*;
import javafx.scene.input.*;
import javafx.scene.canvas.Canvas;
import javafx.scene.canvas.GraphicsContext;
import javafx.stage.Stage;

public class SubHuntViewController extends VBox
{
  private SubHunt sub; // submarine
  private Stage stage;
  private GraphicsContext gc;

  /** Constructor
  * @param sub the Model reference for this game
  * @param stage the Stage for this game
  * @param width the width of the Canvas rendering the game
  * @param height the height of the Canvas rendering the game
  */
  public SubHuntViewController( SubHunt sub,
                                Stage stage, int width, int height )
  {
    this.sub = sub;
    this.stage = stage;
    Canvas canvas = new Canvas( width, height );
    getChildren( ).add( canvas );
    gc = canvas.getGraphicsContext2D( );

    this.setOnMouseClicked( event -> handleMouseEvent( event ) );
    this.setOnTouchPressed( event -> handleTouchEvent( event ) );
  }

  /** handleMouseEvent method
  * @param event the MouseEvent generated by the user
  */
  public void handleMouseEvent( MouseEvent event )
  {
    int x = ( int ) event.getSceneX( );
    int y = ( int ) event.getSceneY( );
    play( x, y );
  }

  /** handleTouchEvent method
  * @param event the TouchEvent generated by the user
  */
  public void handleTouchEvent( TouchEvent event )
  {
    int x = ( int ) event.getTouchPoint( ).getSceneX( );
    int y = ( int ) event.getTouchPoint( ).getSceneY( );
    play( x, y );
  }

  /** play method
  * @param x the x coordinate of the play
  * @param y the y coordinate of the play
  */
  public void play( int x, int y )
  {
    sub.play( x, y );
    sub.draw( gc, x, y );
    stage.setTitle( sub.getStatus( ) );
    if ( sub.isHit( ) )
    {
      this.setOnMouseClicked( null );
      this.setOnTouchPressed( null );
    }
  }
}
```

Description

The constructor receives *SubHunt* and *Stage* references as parameters, which we store in the *sub* and *stage* instance variables at lines 26–27. When the user plays, we use the *sub* reference to call the various methods of the *SubHunt* class to enable play and enforce the rules of the game. When the user interacts with the View by clicking on the window, the Controller captures that information, calls the appropriate method of the *SubHunt* class, and updates the View accordingly. The constructor (lines 17–34) defines and displays the original View. It sets up event handling at lines 32–33 for mouse clicks and touch presses. At line 32, we use a lambda expression to define the listener for mouse events, which will execute the *handleMouseEvent* method.

The *handleMouseEvent* method (lines 36–44) retrieves the *x* and *y* coordinates of the mouse event (lines 41–42) and calls the *play* method (line 43) to enable play. On line 33, we again use a lambda expression to define the listener for touch events, which will execute the *handleTouchEvent* method (lines 46–54), which performs equivalent operations for a touch event.

Inside the *play* method (lines 56–70), we call the *play* method of the *SubHunt* model (line 62) to process the user's action, passing its location. Next, we update the View by drawing the current play (line 63). Then we update the title of the window by getting the updated status, and we display that status in the window title bar by calling the *setTitle* method (line 64). Finally, if the game is over (line 65), we disable event handling (lines 67–68) by passing a *null* argument to the *setOnMouseClicked* and *setOnTouchPressed* methods.

The *PlaySubHunt* class, shown in **Example 17.45**, instantiates a *SubHunt* object (line 16). It then instantiates a *SubHuntViewController* passing the *SubHunt* object we just instantiated as an argument, along with the stage and the game size. The controller extends *VBox*, so we set the controller as the *root* node for our *Scene*. **Figure 17.23** shows a run of this game. At this point, the user has sunk the submarine.

Example 17.45 The *PlaySubHunt* Class

```
/* PlaySubHunt class
   Anderson, Franceschi
*/

import javafx.application. Application;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class PlaySubHunt extends Application
{
  private final int GAME_SIZE = 500;

  @Override
  public void start( Stage stage )
  {
    SubHunt sub = new SubHunt( GAME_SIZE );
    SubHuntViewController root =
      new SubHuntViewController( sub, stage, GAME_SIZE, GAME_SIZE );

    Scene scene = new Scene( root, 500, 500 );
    stage.setTitle( "Play !!" );
    stage.setScene( scene );
    stage.show( );
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

Figure 17.23 A Run of the *SubHunt* Game

Description

In the sub hunt game, we handled mouse clicks and touches. But we didn’t handle mouse movements or touch movements. To illustrate how to handle mouse and touch movements, we build a simple treasure hunt game that is similar to the submarine hunt game. A treasure is hidden somewhere in the window, and the user will try to find it by moving either the mouse or his or her finger inside the window. Depending on how close the mouse or touch is to the treasure, we display a message at the mouse or touch location so the user can eventually find the treasure and win the game. **Figure 17.24** shows the UML diagram for the treasure hunt game.

Figure 17.24 UML Diagram for the Treasure Hunt Game

Description

Again, we first code the Model, a class that encapsulates the functionality of our treasure hunt game (**Example 17.46**). It enables us to create a game of a given size, handle plays, determine when the game is over, and display the status of the game.

Example 17.46 The *TreasureHunt* Class

```
/* TreasureHunt class
*  Anderson, Franceschi
*/

import java.util.Random;
import javafx.scene.canvas.GraphicsContext;
import javafx.scene.paint.Color;
import javafx.scene.text.Font;

public class TreasureHunt
{
 public static int DEFAULT_GAME_SIZE = 300; // side of window
 public static int SIDE = 40; // side of treasure

 private int gameSize;
 private int xCtr; // x coordinate of center of treasure
 private int yCtr; // y coordinate of center of treasure
 private String status = ""; // message
 private boolean gameOver = false;

 /** Constructor
 * @param gameSize the size of the game
 */
 public TreasureHunt( int gameSize )
 {
  if ( gameSize > SIDE )
    this.gameSize = gameSize;
  else
    this.gameSize = DEFAULT_GAME_SIZE;
  // generate treasure center
  Random random = new Random( );
  xCtr = SIDE / 2 + random.nextInt( this.gameSize - SIDE );
  yCtr = SIDE / 2 + random.nextInt( this.gameSize - SIDE );
 }

 /** getGameSize accessor
 * @return gameSize
 */
 public int getGameSize( )
 {
  return gameSize;
 }

 /** isGameOver method
 * @return gameOver
 */
 public boolean isGameOver( )
 {
  return gameOver;
 }

 /** play method
 * @param x the x coordinate of the play
 * @param y the y coordinate of the play
 */
 public void play( int x, int y )
 {
  // is mouse within treasure?
  if ( Math.abs( x - xCtr ) < SIDE / 2
       && Math.abs( y - yCtr ) < SIDE / 2 )
  {
    gameOver = true;
    status = "Found";
  }
  // is mouse within half-length of the treasure?
  else if ( Math.abs( x - xCtr ) < ( 1.5 * SIDE )
            && Math.abs( y - yCtr ) < ( 1.5 * SIDE ) )
    status = "Hot";
  // is mouse within 1 length of the treasure?
  else if ( Math.abs( x - xCtr ) < ( 2 * SIDE )
            && Math.abs( y - yCtr ) < ( 2 * SIDE ) )
    status = "Warm";
  // is mouse within 2 lengths of the treasure?
  else if ( Math.abs( x - xCtr ) < ( 3 * SIDE )
            && Math.abs( y - yCtr ) < ( 3 * SIDE ) )
    status = "Lukewarm";
  else // mouse is not near treasure
    status = "Cold";
 }

 /** draw method
 * @param gc a GraphicsContext reference
 * @param x the x coordinate of the play
 * @param y the y coordinate of the play
 */
 public void draw( GraphicsContext gc, int x, int y )
 {
  gc.setFill( Color.BLUE );
  gc.setFont( new Font( 24 ) );
  gc.clearRect( 0, 0, gameSize, gameSize );
  if ( status.equals( "Found" ) ) // if found, draw treasure
  {
   gc.setFont( new Font( 16 ) );
   gc.setFill( Color.RED );
   gc.fillRect( xCtr - SIDE / 2, yCtr - SIDE / 2, SIDE, SIDE );
   gc.setFill( Color.GREEN );
   gc.fillText( "$$$", xCtr - SIDE / 3, yCtr + SIDE / 6 );
  }
  else
   gc.fillText( status, x, y ); // display current status
 }
}
```

Description

The *status* (line 18) instance variable, a *String*, stores the state of the player's position compared to the location of the treasure. We also define a *boolean* flag variable, *gameOver*, which is initially *false* (line 19); when the user finds the treasure, we will change its value to *true*.

In the constructor, we randomly generate the (*x*, *y*) coordinate for the center of the treasure and store the generated values in the *xCtr* and *yCtr* instance variables (lines 30–33). The *play* method (lines 52–79) sets the value of *status*. If the player is far from the treasure, we set the value of *status* to "Cold." As the user moves closer and closer to the treasure, the value becomes "Lukewarm," then "Warm," and then "Hot," and finally "Found" when the player finds the treasure. If the treasure is found, we set the value of *gameOver* to *true* (line 62).

Like the sub hunt game, the *draw* method (lines 81–101) draws what is happening in the game. We first test if the value of *status* is "Found" (line 91). If it is, the treasure has been found and we reveal its location by drawing it (lines 93–97). If the treasure has not been found, we display *status* at the current mouse or touch location (line 100), determined by the parameters *x* and *y* sent to the *draw* method.

Example 17.47 shows the *TreasureHuntViewController* class. Like the sub hunt example, it combines the View and the Controller. The constructor (lines 19–35) defines and displays the View in a *Canvas* (lines 29–30). The Model is represented by the instance variable *hunt* (line 16), which stores the *TreasureHunt* object sent to the constructor from the *start* method (line 26). In this application, instead of coding the event handler as a *private* inner class, we define our application class as implementing the *EventHandler* interface. As a result, our application is a listener, and we register the listener on itself. Thus, in our class definition, we include the clause *implements EventHandler<InputEvent>* (line 13). We choose the *InputEvent* class because it is a superclass of both *MouseEvent* and *TouchEvent*, and thus we can register both mouse and touch events on our *TreasureHuntViewController*. At lines 33–34, we register this *TreasureHuntViewController* object on itself as an *EventHandler* for both mouse and touch movements.

Example 17.47 The *TreasureHuntViewController* Class

```java
/* TreasureHuntViewController class
*  Anderson, Franceschi
*/

import javafx.event.*;
import javafx.scene.layout.*;
import javafx.scene.input.*;
import javafx.scene.canvas.Canvas;
import javafx.scene.canvas.GraphicsContext;
import javafx.stage.Stage;

public class TreasureHuntViewController extends VBox
       implements EventHandler<InputEvent>
{
  private int width, height;
  private TreasureHunt hunt;
  private GraphicsContext gc;

  /** Constructor
  * @param hunt the model reference
  * @param width the width of the Canvas rendering the game
  * @param height the height of the Canvas rendering the game
  */
  public TreasureHuntViewController( TreasureHunt hunt, int width, int height )
  {
   this.hunt = hunt;
   this.width = width;
   this.height = height;
   Canvas canvas = new Canvas( width, height );
   getChildren( ).add( canvas );
   gc = canvas.getGraphicsContext2D( );

   this.setOnMouseMoved( this );
   this.setOnTouchMoved( this );
  }

  /** handle method
  * @param event the InputEvent generated by the user
  */
  public void handle( InputEvent event )
  {
   int x = -100, y = -100;
   if ( event.getEventType( ) == MouseEvent.MOUSE_MOVED )
   {
     MouseEvent mEvent = ( MouseEvent ) event ;
     x = ( int ) mEvent.getSceneX( );
     y = ( int ) mEvent.getSceneY( );
   }
   else if ( event.getEventType( ) == TouchEvent.TOUCH_MOVED )
   {
    TouchEvent tEvent = ( TouchEvent ) event ;
    x = ( int ) tEvent.getTouchPoint( ).getSceneX( );
    y = ( int ) tEvent.getTouchPoint( ).getSceneY( );
   }

   hunt.play( x, y );

   hunt.draw( gc, x , y );
   if ( hunt.isGameOver( ) )
   {
     this.setOnMouseMoved( null );
     this.setOnTouchMoved( null );
     Stage stage = ( Stage ) getScene( ).getWindow( );
     stage.setTitle( "Thank you for playing" );
   }
  }
}
```

Description

In this game, the events we want to handle are the user moving the mouse or his or her finger on the screen. Because *TreasureHuntViewController* implements the *EventHandler* interface, we must provide a *handle* method, which we do at lines 37–66. Because the ways we retrieve the *x* and *y* coordinates of a mouse event and a touch event are different, we first test if the event is a mouse event (line 43) or a touch event (line 49) by calling the *getEventType* method, inherited from the *Event* class. We compare the return value to the appropriate constant of either the *MouseEvent* class or the *TouchEvent* class. Both constants are shown in **Table 17.45**. We type cast the event to the appropriate event at lines 45 and 51, then retrieve the *x* and *y* coordinates of the mouse or touch movement.

Useful *EventType* Constants of the *MouseEvent* and *TouchEvent* Classes

Class	Constant
`MouseEvent`	`MOUSE_MOVED`
constant identifying a mouse move event	
`TouchEvent`	`TOUCH_MOVED`
constant identifying a touch move event	

Description

Then we call the *play* method of the *TreasureHunt* model (line 56) to process the play. Next, we display the result of the current move (line 58) by calling the *draw* method of *TreasureHunt*, passing the *GraphicsContext* reference *gc* and the mouse or touch location. If the game is over (i.e., the treasure has been found), we remove this object, the current *TreasureHuntViewController*, as a listener (lines 61–62) for both mouse and touch moving events.

At lines 63–64, we update the title of the window to reflect the fact that the user has found the treasure and the game is over. In order to do that, we need a reference to the *Stage* of this *VBox*, so we can call the *setTitle* method. The *getScene* method, inherited by *VBox* from the *Node* class, returns the *Scene* containing this *Node*, the *TreasureHuntViewController*. With it, we call the *getWindow* method in order to get a reference to the window, which represents the stage. *Stage* is a subclass of *Window*, so we cast the return value of *getWindow* to a *Stage* in order to get a reference to the stage. **Table 17.46** shows the *getScene* and *getWindow* methods.

Useful Classes and Methods to Retrieve the Stage

Class	Method
`Node`	`Scene getScene( )`
returns the *Scene* containing this *Node*	
`Scene`	`Window getWindow( )`
returns the window for this *Scene*	

Description

Finally, the *PlayTreasureHunt* class, shown in **Example 17.48**, includes the *main* method to create a *TreasureHuntViewController* application showing a *TreasureHunt* game. **Figures 17.25** and **17.26** show the program running. In Figure 17.25, the user is getting close to the treasure, and in Figure 17.26, the user has found the treasure.

Example 17.48 The *PlayTreasureHunt* Class

```
/* PlayTreasureHunt class
   Anderson, Franceschi
*/

import javafx.application.Application;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class PlayTreasureHunt extends Application
{
  private final int GAME_SIZE = 500;

  @Override
  public void start( Stage stage )
  {
    TreasureHunt th = new TreasureHunt( GAME_SIZE );
    TreasureHuntViewController root =
      new TreasureHuntViewController( th, GAME_SIZE, GAME_SIZE );

    Scene scene = new Scene( root, GAME_SIZE, GAME_SIZE );
    stage.setTitle( "Play !!" );
    stage.setScene( scene );
    stage.show( );
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

Figure 17.26 The User Has Found the Treasure

Description

In both the sub hunt and treasure hunt examples, the Model is reusable in another application. However, the View and the Controller are combined in the same class and are not reusable. Later in the chapter, we will make the View reusable too.

17.15 Using a List to Display a Pie Chart

JavaFX includes classes that make it easy to display various types of charts, including line charts, pie charts, and bar charts. To display a chart, we first create a list that stores the data we want to display. We then assign that data to the appropriate chart object. After we include the chart object in a scene, the chart draws itself automatically. The *ObservableList* interface, from the *javafx.collections* package, is a list that can be linked to a GUI component, such as a *ComboBox*. Whenever the values in the list change, the associated GUI component is automatically updated to reflect those changes. Several chart classes, such as *PieChart* and *BarChart*, can be constructed by linking their data to an *ObservableList*.

In this example, we use the *PieChart* class to display a pie chart, a filled circle composed of colored slices, where each slice represents a percentage of the whole pie. The *PieChart* constructor, listed in **Table 17.47**, accepts an *ObservableList* of *PieChart.Data* as its only parameter. *PieChart.Data* is an inner class of *PieChart* and each object represents one slice of the pie chart. A slice is defined by its label and its value. The *PieChart.Data* constructor shown in Table 17.47 accepts a *String* parameter for the label and a *double* parameter for the value.

PieChart.Data and *PieChart* Constructors

Package	javafx.scene.chart
***PieChart.Data* and *PieChart* Constructors**	
`PieChart.Data( String name, double value )`	
creates a *PieChart.Data*, a slice of a *PieChart*; the slice value is *value* and its label is *name*	
`PieChart( ObservableList<PieChart.Data> data )`	
creates a *PieChart* using *data* as its data for all its slices	

Description

To display a pie chart, we do the following:

- Create a list of *PieChart.Data* objects.
- Convert that list to an *ObservableList*.
- Create a *PieChart* associated with that *ObservableList*.
- Create a *Scene* with that *PieChart*.

Example 17.49 creates a pie chart displaying the various parts of a monthly budget so we can visualize the percentage of the total for each category. At lines 11–14, we declare two arrays, *categories* and *expenses*, which hold the labels and the corresponding values for the pie chart slices. At lines 19–22, we create and fill *list*, an *ArrayList* of *PieChart.Data*. Each *PieChart.Data* is defined with a label from the *categories* array and a value from the *expenses* array (line 22). At lines 23–24, we call the *observableList* method of the *FXCollections* class, shown in **Table 17.48**, to construct the *ObservableList* *pieChartData* from that *ArrayList*. The *ArrayList* class *implements* the *List* interface, and thus an *ArrayList* can be used as an argument of the *observableList* method.

Example 17.49 An Application to Display a Pie Chart

```java
import java.util.ArrayList;
import javafx.application.Application;
import javafx.collections.FXCollections;
import javafx.collections.ObservableList;
import javafx.scene.chart.*;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class MonthlyBudgetPieChart extends Application
{
  private String [ ] categories
    = { "Rent", "Food", "Phone", "Entertainment", "Utilities" };
  private double [ ] expenses
    = { 800, 450, 72.50, 200, 90 };

  @Override
  public void start( Stage stage )
  {
    // Create a PieChart.Data of monthly expenses
    ArrayList<PieChart.Data> list = new ArrayList<PieChart.Data>( );
    for ( int i = 0; i < expenses.length; i++ )
      list.add( new PieChart.Data( categories[i], expenses[i] ) );
    ObservableList<PieChart.Data> pieChartData
      = FXCollections.observableList( list );

    // Create a PieChart with pieChartData
    PieChart chart = new PieChart( pieChartData );
    chart.setTitle( "Monthly Budget" );

    // Define the scene and stage
    Scene scene = new Scene( chart, 500, 400 );
    stage.setScene( scene );
    stage.setTitle( "Pie Chart for Monthly Expenses" );
    stage.show( );
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

The *observableList* Method of the *FXCollections*

The *observableList static* Method of the *FXCollections* Class

Return value	Method name and argument list
`ObservableList<E>`	`observableList( List<E> list )`
constructs and returns an *ObservableList* composed of elements of type E from *list*. Changes to that *ObservableList* will be reflected in components that are registered on that *ObservableList*.	

Description

At lines 26–28, we construct the *PieChart* chart with *pieChartData* and set its title. At lines 30–34, we construct a *Scene* with the *PieChart* (line 31) and set the *Stage* with that *Scene*. The *PieChart* class inherits from the *Parent* class, and thus a *PieChart* can be used to construct a scene. **Figure 17.27** shows the pie chart.

Figure 17.27 Displaying a Pie Chart for a Monthly Budget

Description

In the next example, we show how a graphical component redraws itself automatically when the observable list that it is bound to changes.

17.16 Using a List to Display a Dynamic Bar Chart

In this example, we display a bar chart that displays projected values of stocks and bonds over 4 years for an initial investment of $100. The *BarChart* class can be used to create a two-dimensional bar chart. A *BarChart* is defined using a horizontal axis, a vertical axis, and a list consisting of one or two *series* of data, each series representing a single-dimensional list of data. Thus, if we use only one series in that list, we can define a one-dimensional bar chart as a special case of a two-dimensional bar chart. Our example uses two series of data, one for stocks and one for bonds. The projected values of the bonds are fixed, but the projected values of the stocks toggle between two sets of values, depending on what growth rate we use. The user can toggle between the two sets of values by clicking on a button. The *BarChart* is bound to an *ObservableList*. When the user clicks on the button, we change the data inside the

ObservableList to the alternate set of values. Because the *BarChart* is bound to the *ObservableList*, it is automatically updated. **Figures 17.28** and **17.29** show both states of the *BarChart*.

Figure 17.28 The Stocks and Bonds Using the First Set of Values for Stocks

Description

Figure 17.29 The Stocks and Bonds Using the Second Set of Values for Stocks

Description

Before explaining how we can create and draw a bar chart, we define our Model. It includes three classes:

- *Investment*, an *abstract* superclass: An *Investment* has a type (Stocks or Bonds), an original amount, a growth rate, and the number of years over which to compute the value of the original amount as we apply the growth rate.
- *Bonds*, a subclass of *Investment*: The growth rate is constant.
- *Stocks*, a subclass of *Investment*: The growth rate toggles between two constant values.

Examples 17.50, **17.51**, and **17.52** show these three classes. The *updateAmounts* method (lines 76–83) of the *Investment* class updates the instance variable *amounts* based on the growth rate. *Investment* specifies the *update* method as *abstract*. It is meant to update the growth rate and then update the resulting cash flow. In this example, a *Bonds* has a constant growth rate; thus, its *update* method (lines 19–25 of Example 17.51) does nothing, that is, it leaves the growth rate unchanged. The *update* method of the *Stocks* class (lines 20–31 of Example 17.52) makes the growth rate of a *Stocks* investment toggle between two constant values (lines 7–8).

Example 17.50 The *Investment* Class

```
/** abstract Investment class
*   Anderson, Franceschi
*/

public abstract class Investment
{
  public static final int DEFAULT_YEARS = 4;
  public static final double BEGIN_INVEST_AMOUNT = 100;
  private double [ ] amounts;
  private int years;
  private double growthRate;
  private String type;

  /* Constructor
  * @param years, an int, the new value of years
  * @param type, a String, the new value for the investment type
  */
  public Investment( int years, String type )
  {
    if ( years < 1 )
      this.years = DEFAULT_YEARS;
    else
      this.years = years;

    amounts = new double[this.years];
    amounts[0] = BEGIN_INVEST_AMOUNT;

    this.type = type;
  }

  /* getAmounts method
  * @return a copy of amounts, a double [ ]
  */
  public double [ ] getAmounts( )
  {
    double [ ] temp = new double[amounts.length];
    for ( int i = 0; i < amounts.length; i++ )
        temp[i] = amounts[i];
    return temp;
  }

  /* Accessor method for years
  * @return number of years
  */
  public int getYears( )
  {
    return years;
  }

  /* Accessor method for type
  * @return investment type
  */
  public String getType( )
  {
    return type;
  }

  /* Accessor method for growthRate
  * @return growthRate
  */
  public double getGrowthRate( )
  {
    return growthRate;
  }

  /* Mutator method for growthRate
  * @param growthRate, the new value for growthRate
  * @return a reference to this object
  */
  public Investment setGrowthRate( double growthRate )
  {
    this.growthRate = growthRate;
    return this;
  }

  /* updateAmounts method
  * updates amounts based on growthRate
  */
  public void updateAmounts( )
  {
    for ( int i = 1; i < amounts.length; i++ )
      amounts[i] = amounts[i-1] * ( 1 + growthRate );
  }

  /* update abstract method
  */
  public abstract void update( );
}
```

Description

Example 17.51 The *Bonds* Class

```
/** Bonds class
*   Anderson, Franceschi
*/

public class Bonds extends Investment
{
  private final double BOND_GROWTH_RATE = .03;

  /* Constructor
  * @param years the new number of years
  */
  public Bonds( int years )
  {
    super( years, "Bonds" );
    setGrowthRate( BOND_GROWTH_RATE );
    updateAmounts( );
  }

  /* update method
  * do nothing method: Leaves the growth rate unchanged
  */
  public void update( )
  {
    // growth rate does not change
  }
}
```

Description

Example 17.52 The *Stocks* Class

```java
/** Stocks class
*   Anderson, Franceschi
*/

public class Stocks extends Investment
{
  private static final double SLOW_GROWTH_RATE = .02;
  private static final double FAST_GROWTH_RATE = .07;

  /* Constructor
  * @param years the new number of years
  */
  public Stocks( int years )
  {
    super( years, "Stocks" );
    setGrowthRate( SLOW_GROWTH_RATE );
    updateAmounts( );
  }

  /* update method
  *  toggles the growth rate and updates amounts accordingly
  */
  public void update( )
  {
    if ( Math.abs( getGrowthRate( ) - SLOW_GROWTH_RATE ) < 0.0001 )
      setGrowthRate( FAST_GROWTH_RATE );
    else
      setGrowthRate( SLOW_GROWTH_RATE );

    updateAmounts( );
  }
}
```

Description

The *XYChart* class, which uses generics, is the base class for charts involving two axes. *XYChart* is the direct superclass of *BarChart*. The *XYChart* class provides the functionality to draw the two axes and the contents of the chart. It contains two inner classes:

- *XYChart.Data*, which encapsulates a single data item to be used in two-axis charts
- *XYChart.Series*, a series, or list, of *XYChart.Data* items

XYChart, *BarChart*, *XYChart.Data*, and *XYChart.Series* all use two types of objects; the first object serves as a label for the second. Thus, often, the first type is *String* and the second type is *Number*. The *Number* class is the superclass for all numeric wrapper classes (*Integer*, *Double*, ..) and thus can be used with all primitive integer data types since Java supports both autoboxing (automatic conversion from a primitive type to a wrapper type) and unboxing (automatic conversion from a wrapper type to a primitive type).

Typically, the observable list bound to a bar chart is a list of lists, that is, it is a two-dimensional data structure. In our example, the observable list contains a list of *XYChart.Series* items. Each *XYChart.Series* is a list of *XYChart.Data* items. Each *XYChart.Data* item contains two elements: the year, which is a *String*; and the value, which is a *double*. The *String* serves as a label for the value. For example, our initial two *XYChart.Series* contain the following data:

Bonds series: “2020”,100.0 “2021”,103.0 “2022”,106.09 “2023”,109.2727
Stocks series: “2020”,100.0 “2021”,107.0 “2022”,114.49 “2023”,122.5043

Description

The first series is the bonds series, which contains four data items; each data item includes a year and a value. The second series is the stocks series and also contains four data items. Both series are parallel to each other; not only do the two series contain the same number of items, four, but the value of the year for two corresponding data items is the same. In this way, the bar chart not only displays the values, but also enables a quick visual comparison between the two series.

Example 17.53 shows our *BarChartView* class. It extends *BorderPane* and contains a *BarChart* in its center and a button at the bottom. The *BarChart bc* and the *ArrayList series* are defined at lines 20 and 22. The *addBarChart* method (lines 40–71), called by the constructor at line 37, creates the bar chart and places it in the center position of the *BorderPane*. Inside the *addBarChart* method, we do the following:

Example 17.53 A View Class Displaying a Bar Chart

```
/** BarChartView class
* Layout using a BorderPane's
* bottom and center positions.
* The bottom HBox is made up of one button.
* The center position is made up of a BarChart.
* Anderson, Franceschi
*/

import java.util.ArrayList;
import javafx.event.*;
import javafx.geometry.Pos;
import javafx.scene.control.*;
import javafx.scene.layout.*;
import javafx.scene.chart.*;

public class BarChartView extends BorderPane
{
  private HBox buttonPanel; // bottom, holds button
  private Button button;
  private BarChart<String, Number> bc; // center, holds chart

  ArrayList<XYChart.Series<String, Number>> series;
  private int startingYear;

  public BarChartView( int startingYear, Investment [ ] investments )
  {
    super( );
    this.startingYear = startingYear;

    buttonPanel = new HBox( );
    button = new Button( );
    button.setText( "NEXT SCENARIO" );
    buttonPanel.setAlignment( Pos.CENTER );
    buttonPanel.getChildren( ).add( button );
    setBottom( buttonPanel );

    addBarChart( investments );
  }

  public void addBarChart( Investment [ ] investments )
  {
    // Create a BarChart for investment
    CategoryAxis xAxis = new CategoryAxis( );
    NumberAxis yAxis = new NumberAxis( );
    bc = new BarChart<String, Number>( xAxis, yAxis );
    bc.setTitle( "Investment Scenarios" );
    xAxis.setLabel( "Year" );
    yAxis.setLabel( "Value" );

    // Create an ArrayList of XYChart.Series using investments data
    series = new ArrayList<XYChart.Series<String, Number>>( );

    for ( int i = 0; i < investments.length; i++ )
    {
      XYChart.Series<String, Number> currentInvestmentSeries
        = new XYChart.Series<String, Number>( );
      currentInvestmentSeries.setName( investments[i].getType( ) );

      double [ ] currentAmounts = investments[i].getAmounts( );
      for ( int j = 0; j < currentAmounts.length; j++ )
      {
        currentInvestmentSeries.getData( ).add(
           new XYChart.Data<String, Number>(
             String.valueOf( startingYear + j ), currentAmounts[j] ) );
      }
      series.add( currentInvestmentSeries );
    }
    // Fill BarChart with XYChart.Series array
    bc.getData( ).addAll( series );
    setCenter( bc );
  }

  public void update( Investment [ ] investments )
  {
    // update investments
    for ( int i = 0; i < investments.length; i++ )
    {
      // do not update bonds series
      if ( ! investments[i].getType( ).equals( "Bonds" ) )
      {
        // retrieve series
        XYChart.Series<String, Number> currentInvestmentSeries
          = series.get( i );

        // change data of series
        currentInvestmentSeries.getData( ).clear( );
        double [ ] currentAmounts = investments[i].getAmounts( );
        for ( int j = 0; j < currentAmounts.length; j++ )
        {
           currentInvestmentSeries.getData( ).add(
             new XYChart.Data<String, Number>( ""
               + ( startingYear + j ), currentAmounts[j] ) );
        }

        // update series
        series.set( i, currentInvestmentSeries );
      }
    }
  }

  public void setButtonListener( EventHandler<ActionEvent> eh )
  {
    button.setOnAction( eh );
  }
}
```

Description

1. Instantiate an empty *BarChart* with an *x* axis and a *y* axis (lines 42–48).
2. Create an *ArrayList* of *XYChart.Series* objects (lines 50–67).
3. Access the data of the *BarChart* and add the *ArrayList* to it (lines 68–69).
4. Place the *BarChart* at the center of the *BorderPane* (line 70).

Table 17.49 lists one of the *BarChart* constructors. Since the constructor accepts two *Axis* parameters, we first need to create two axes for our bar chart. The *CategoryAxis* and *NumberAxis* classes are subclasses of the *abstract Axis class*:

- *CategoryAxis* encapsulates an axis that displays categories where each value represents a unique category (tick mark) along the axis. In this example, we use a *CategoryAxis* to show the years.
- *NumberAxis* encapsulates an axis that plots a range of numbers with major tick marks every “tickUnit.” We can use any *Number* type with this axis, *Integer, Double*, etc. … In this example, we use a *NumberAxis* for the values.

A Constructor of the *BarChart* Class

Package	**javafx.scene.chart**
`BarChart( Axis<X> xAxis, Axis<Y> yAxis )` creates a *BarChart* with the two axes. One of the axes should be a *CategoryAxis*, the other one a *ValueAxis*. Their order determines if the bar chart is horizontal or vertical.	

Description

At lines 42–44, we create the two axes and the *BarChart*. We set the title of the bar chart at line 46 and the labels of the axis at lines 47–48.

Next, we instantiate *series* (line 51), an *ArrayList* of *XYChart.Series<String, Number>*. For each *Investment* reference in *investments*, we create an *XYChart.Series* and add it to *series*. **Table 17.50** shows an *XYChart.Series* constructor, as well as an *XYChart.Data* constructor. There are only two elements in *investments* in this example, one *Bonds* object and one *Stocks* object. At lines 55–56, we instantiate an *XYChart.Series<String, Number>* named *currentInvestmentSeries*. At line 57, we set the name that will be displayed for this *currentInvestmentSeries* to the type of investment of the current *Investment* element. To do this, we call the *setName* method shown in **Table 17.51**. Next, we set the values in *currentInvestmentSeries* to the values in the current *Investment* element. After we retrieve the array of values for the current *Investment* element and assign it to the array *currentAmounts*, we loop through *currentAmounts* at lines 60–65 and create an *XYChart.Data* item for each value in *currentAmounts* (lines 63–64). We set the label of each *XYChart.Data* item to the current year and its value to the current amount. We compute the current year by adding the counting index of the loop, *j*, to *startingYear*. After the loop, we add *currentInvestmentSeries* to the *series ArrayList* at line 66. At line 69, we call *getData* to retrieve the *ObservableList* associated with *bc*. At this point, the observable list is empty, so we call the *addAll* method to set the observable list to *series*. When we add *bc* to the center of the *BorderPane* at line 70, the bar chart is displayed.

XYChart.Series and *XYChart.Data* Constructors

Package **javafx.scene.chart**

`XYChart.Series( )`

creates an *XYChart.Series* that will contain *XYChart.Data* items

`XYChart.Data( X xValue, Y yValue )`

creates data for the two axes of the chart; the X and Y types should match the X and Y types for the *x* and *y* axes

Description

The *getData* and *setName* Methods of the *XYChart.Series* Class

Return Value	Method name and argument list
`ObservableList<XYChart.Data<X, Y>>`	`getData( )`
returns the *ObservableList* of data items that make up this series	
`void`	`setName( String value )`
sets the name to be displayed for this series	

Description

The *update* method (lines 73–99) is called by the controller when the view needs to be updated because the user updated the data in the model. The *update* method updates the data inside the *ArrayList series* based on the state of the model. Since the *BarChart bc* is bound to *series*, the bar chart will be updated automatically. Since bond values do not change, we only update the data for investments that are not bonds (line 79) when we loop through *investments* at lines 76–98. We first retrieve the current *XYChart.Series* at lines 81–83 and assign it to the reference *currentInvestmentSeries*. Because we add new *XYChart.Data* items storing the updated data to *currentInvestmentSeries* (lines 90–92), we first need to empty *currentInvestmentSeries* by calling the *clear* method (line 86). If we do not, we would be adding new *XYChart.Data* items to the existing ones. At lines 95–96, we update the current element of *series*.

The *setButtonListener* method (lines 101–104), meant to be called by the controller, sets up event handling for the button.

Example 17.54 shows the *BarChartViewController* class, the controller for our bar chart application. It includes the instance variables *investments* and *view* (lines 10–11), which represent the View and the Model for the application, respectively. The *BarChartViewController* class implements *EventHandler* and is its own event handler. We set up event handling at line 18 and handle the event in the *handle* method (lines 21–28) by first updating the Model (lines 23–25) and then updating the View (lines 26–27).

Example 17.54 The Controller for the Bar Chart Application

```
 1 /** BarChartViewController class
 2 *   Anderson, Franceschi
 3 */
 4
 5 import javafx.event.*;
 6 import javafx.scene.control.*;
 7
 8 public class BarChartViewController implements EventHandler<ActionEvent>
 9 {
10   private BarChartView view;
11   private Investment [ ] investments;
12
13   public BarChartViewController( BarChartView view,
14                                  Investment [ ] investments )
15   {
16     this.investments = investments;
17     this.view = view;
18     ( this.view ).setButtonListener( this );
19   }
20
21   public void handle( ActionEvent event )
22   {
23     // update the model
24     for ( int i = 0; i < investments.length; i++ )
25       investments[i].update( );
26     // update the view
27     view.update( investments );
28   }
29 }
```

Description

Example 17.55 shows the *InvestmentApplication* class. We create an array of two *Investment* objects at lines 14–18, create the View for the app at line 19, and create the Controller for the application at lines 27–28. We specify that *2020* is the starting year for our data (line 19).

Example 17.55 The *InvestmentApplication.java* File

```
/** InvestmentApplication class
*   Anderson, Franceschi
*/

import javafx.application.Application;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class InvestmentApplication extends Application
{
  @Override
  public void start( Stage stage )
  {
    int years = 4;
    Stocks stocks = new Stocks( years );
    Bonds bonds = new Bonds( years );
    Investment [ ] investments = { bonds, stocks };

    BarChartView root = new BarChartView( 2020, investments );

    Scene scene = new Scene( root, 540, 510 );
    stage.setTitle( "Financial Projections" );
    stage.setScene( scene );
    stage.show( );

    BarChartViewController controller
      = new BarChartViewController( root, investments );
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

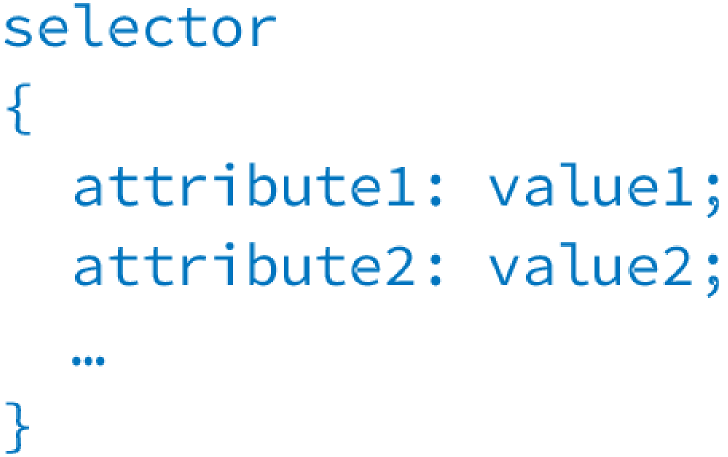
17.17 Using a Style Sheet to Style the View

GUI components come with a default style. For example, the background color is white and the text is black. Labels have a rectangular shape, and buttons have a rectangular shape with rounded corners. We can create our own style and customize the look and feel of our application. It is typical to define a style in a separate file, thus separating the contents of the GUI from its style. In this way, it is easier to edit and separately maintain the contents of the GUI and its style; we can modify the style file, also called a **style sheet**, and the new style is automatically applied to the app.

Earlier in the chapter we introduced CSS. JavaFX supports **Cascading Style Sheets** (**CSS**), a language that describes how a document should be styled. CSS is often used with web pages, and the JavaFX version of CSS is similar to the CSS used with web pages.

The general syntax to style a GUI component in a style sheet is:



```
selector
{
   attribute1: value1;
   attribute2: value2;

   …
}
```

Description

The *selector* can be a GUI component, such as a *Label*, but it can also be something identifying a group of components or a specific component. Attributes are prefixed with *-fx-*.

To illustrate this, we add styles to our Simple Math application, shown previously in Examples 17.5 through 17.8. **Example 17.56** shows a style sheet for the Simple Math application. At lines 6–10, we style all the labels so their background color is deepskyblue and their foreground color is blue. If we want to give a specific style to a single component, we can give it an id in the FXML file and style that id in the style sheet. In Example 17.6, we gave the id result to the bottom label, which displays the result of the Math operation. To style that label differently from the other labels, we define a style for its id. A selector for an id starts with the # sign followed by the id. At lines 12–16, we style the component with id result so that its background color is aqua (line 14) and its text is bold (line 15). Note that the background color of the bottom label is styled twice: once at line 8 where all the labels are styled, and another time at line 14 where the id result is styled. The id's style prevails over the component's general style. Thus, the background color of the bottom label is aqua. However, because the id's style does not redefine the foreground color, the foreground color defined for all the labels at line 9 applies to the bottom label.

Finally, at lines 18–21, we define the background color of the buttons when the mouse hovers over them as green.

Example 17.56 A JavaFX Style Sheet for the Simple Math Application

```
 1 VBox
 2 {
 3   -fx-background-color: skyblue;
 4 }
 5
 6 Label
 7 {
 8   -fx-background-color: deepskyblue;
 9   -fx-text-fill: blue;
10 }
11
12 #result
13 {
14   -fx-background-color: aqua;
15   -fx-font-weight: bold;
16 }
17
18 Button:hover
19 {
20   -fx-background-color: #00FF00;
21 }
```

Description

To apply our style sheet to our application, we link the style sheet to the scene. **Example 17.57** shows the modified *SimpleMathPractice* class. We link the style sheet at line 23 by calling the *getStylesheets* method of the *Scene* class. If we have more than one style sheet, we can add as many as desired using this method.

Example 17.57 Importing a Style Sheet

```
/*  Simple Math Operations Using Buttons
    Anderson, Franceschi
*/

import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.VBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class SimpleMathPractice extends Application
{
  @Override
  public void start( Stage stage ) // throws Exception
  {
    try
    {
      URL url =
         getClass( ).getResource( "fxml_simple_math.fxml" );
      VBox root = FXMLLoader.load( url );
      Scene scene = new Scene( root, 300, 275 );
      scene.getStylesheets( ).add( "simple_math.css" );
      stage.setTitle( "Simple Math" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      e.printStackTrace( );
    }
  }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

Figures 17.30 and **17.31** show the application running as the user first hovers over the “Cube” button and then clicks on it.

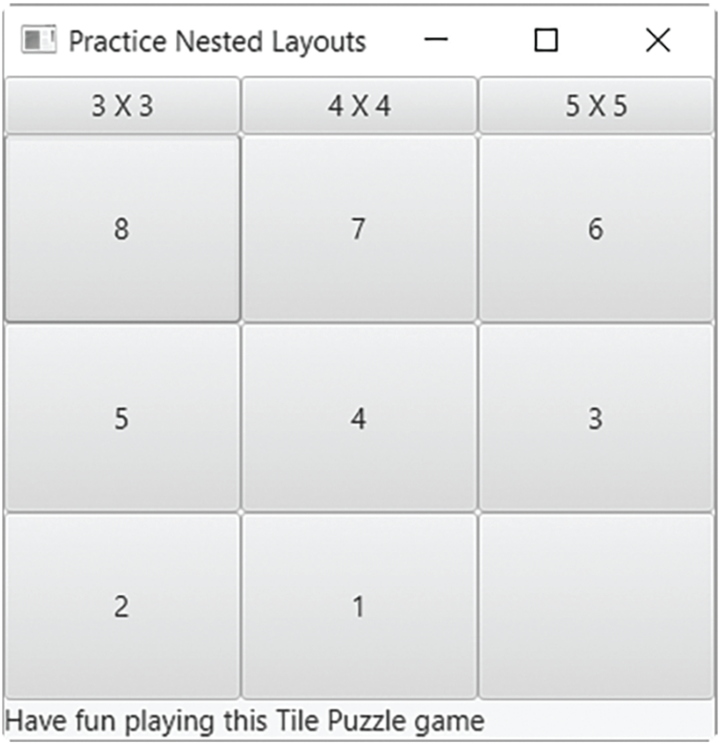
Practice Nested Layouts

Have fun playing this Tile Puzzle game



Have fun playing this Tile Puzzle game

17.18 Programming Activity 2: Working with Layout Containers

In this Programming Activity, you will complete the implementation of a version of the Tile Puzzle game using a more complex GUI. As it stands now, the application compiles and runs, but it is missing a lot of code. **Figure 17.32** shows the window that will open when you run the application without adding your code. Once you have completed the five tasks of this Programming Activity, you should see the window in **Figure 17.33** when you run your program and click on the “3-by-3” button. When you click on one of the buttons labeled “3-by-3,” “4-by-4,” or “5-by-5,” the tile puzzle will reset to a grid of that size.

Figure 17.32 The Starting Window When Running the Prewritten Code

Description

Figure 17.33 The Starting Window When the Activity Is Completed

Description

In addition to the *TilePuzzle* class, we provide you with a prewritten *GameView* class, which encapsulates a View for the Tile Puzzle game. We have implemented the *GameView* class as a *GridPane* container, so you can add it to another layout container, such as a *BorderPane*. It has two important methods, shown in **Table 17.52**. Thus, your job in this Programming Activity is not to write the game code, but to organize components in a window.

The *GameView* Class API

Constructor

`GameView( int nSides )`

instantiates a tile puzzle View having an *nSides*-by-*nSides* grid

Return value	**Method name and argument list**
`void`	`setUpGame( int nSides )`

resets the grid as an *nSides*-by-*nSides* grid

Description

You need to edit the *NestedLayoutPractice* class, which *extends BorderPane*. Your job is to:

1. Declare an HBox named *top* and three *Buttons* that will be added to the *top* position of the *BorderPane*.
2. Set the layout containers for the *center* and *top* positions.
3. Add the *top* and the *gameView* layout containers to the

BorderPane.

4. Code an appropriate *private* listener class.
5. Instantiate the listener and register it on the appropriate components.

Instructions

Copy the source files in the Programming Activity 2 folder for this chapter to a folder on your computer.

1. Write the code to declare the needed instance variables. Load the *NestedLayoutPractice.java* source file and search for five asterisks in a row (*****). This will position you at the instance variables declaration.

```
// ***** Task 1: declare an HBox named top
// also declare three Button instance variables
// that will be added to the HBox top.
// These buttons will determine the grid size of the game:
// 3-by-3, 4-by-4, or 5-by-5

// task 1 ends here
```

   Description

2. Next, write the code to set the layout manager of the window and add the component *gameView* in the center position of the window. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you inside the constructor.

```
// ***** Task 2: student code starts here
// instantiate the GameView object

// add gameView to the center of this BorderPane

// task 2 ends here
```

   Description

3. Next, write the code to instantiate the *HBox* top component, instantiate the buttons from task 1, add them to *top*, and

finally add *top* at the top position of our *BorderPane*. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you inside the constructor.

```
// ***** Task 3: Student code restarts here
// instantiate the HBox component named top
// instantiate the Buttons that determine the grid size

// add the buttons to HBox top
// make them take all the available space
// add HBox top to this BorderPane as its top component

// task 3 ends here
```

Description

4. Next, write the code for the *private* inner class that implements the appropriate listener. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you between the constructor and the end of the class.

```
// ***** Task 4: Student code restarts here
// create a private inner class that implements EventHandler
// your method should identify which of the 3 buttons
//    was the source of the event
// depending on which button was pressed,
//    call the setUpGame method of the GameView class
//    with arguments 3, 4, or 5
// the API of that method is:
//   public void setUpGame( int nSides )

// task 4 ends here
```

Description

5. Next, write the code to declare and instantiate a listener, and register it on the appropriate components. In the *NestedLayoutPractice.java* source file, search again for five asterisks in a row (*****). This will position you inside the constructor.

```
// ***** Task 5: Student code restarts here
// Note: search for and complete Task 4 before performing this task
// declare and instantiate an EventHandler

// register the handler on the 3 buttons
// that you declared in Task 1

// task 5 ends here
```

Description

After completing each task, compile your code.

When you have finished writing all of the code, compile the source code and run *NestedLayoutPracticeApplication*. Try clicking on the three buttons that you added.

DISCUSSION QUESTIONS

1. Identify the various layout containers you used and the screen positions they occupy.
2. Explain why the left and right positions are not shown on the window.

CHAPTER REVIEW

17.19 Chapter Summary

- A Graphical User Interface (GUI) allows the user to enter data and initiate actions for an application by entering text into boxes; pressing buttons; moving the thumb of a slider; or selecting items from a list, a set of radio buttons, or checkboxes.
- Applications with GUIs are usually easier to learn and use because the interface is familiar to the user.
- JavaFX is a set of classes included with Java SE for creating GUIs.
- The top-level structure in a JavaFX application is the stage, which corresponds to a window. A stage can have one or more scenes, which are top-level containers for nodes that make up the window contents. A node can be a user interface control, such as a button or drop-down list; a layout container; an image or other media; a graphical shape; a web browser; a chart; or a group.
- JavaFX applications can be built in several ways. If we know which controls our interface needs and how they should be arranged, we can specify the layout, controls, and their properties using FXML, a scripting language based on XML. For more complicated GUIs or for dynamic GUIs where the number or type of control is determined at runtime, we can control the number, type, properties, and

positioning of controls programmatically.

- A JavaFX application extends the *Application* class and, at minimum, implements the *start* method.
- Some JavaFX GUI controls are *Label*, *TextField*, *Button*, *RadioButton*, *CheckBox*, *ComboBox*, and *Slider*. These controls inherit from the *Node* class.
- Controls can be arranged in a window using layout containers, such as *HBox*, *VBox*, *BorderPane*, *GridPane*, or *StackPane*. Layout containers can be nested.
- GUI applications use an event-driven model, where the user determines which functions are performed by interacting with the application controls, consequently firing events. To handle an event, we register our interest in being notified of the event and provide code: an event handler or listener, to be executed when the event occurs.
- JavaFX supports and encourages the Model-View-Controller architecture in GUI applications. The Model manages the data of the application and its state. The View presents the user interface. The Controller handles events generated by the user and communicates those changes to the Model, which updates its state accordingly and communicates any changes back to the Controller. The Controller then updates the View to reflect those changes.
- FXML can be used to define not only the application's layout containers, GUI controls, and their properties, but also the controller class and the method to be executed when an event fires.
- An *ActionEvent* object is created when the user clicks a button, selects an item from a list or a menu, or presses the *Enter* key in a *TextField*. The *getSource* method of the *ActionEvent* object returns a reference to the control that fired the event.
- To make *RadioButtons* mutually exclusive, we define a *ToggleGroup* and then set each *RadioButton*'s *toggleGroup* property accordingly.
- A Controller can have an *initialize* method, which is called after the scene graph has been created. The *initialize* method can be used to add nodes and set properties that

could not be fully defined in the FXML file. In the *initialize* method, we also can retrieve initial values from the Model and update the View accordingly so that the View reflects the initial state of the Model when the application starts.

- We put *ComboBox* items into an *ObservableList* and use the *SingleSectionModel* to manage the selection of items.
- The *Slider* control is capable of displaying a set of continuous values along a horizontal or vertical line called a track. The user “slides” the knob, called the thumb, along the track to select a value. We can set properties of a *Slider* to display tick marks and tick values.
- An event handler for a *Slider* control needs to implement the *ChangeListener<T>* interface.
- Defining our application’s GUI components, properties, and event handlers programmatically is useful for dynamic GUIs where the number or type of controls is not known until run time, or when we have an array of controls that are handled similarly.
- A *VBox* is a layout container that arranges its components vertically.
- An *HBox* is a layout container that arranges its components horizontally.
- A *GridPane* can be visualized as a table made up of cells in rows and columns. Each cell can contain one component. These cells can have different sizes, which we specify using row and column constraints.
- The *Alert* class enables us to construct and display dialog boxes.
- A *BorderPane* layout container organizes its nodes into five positions—*top*, *bottom*, *left*, *right*, and *center*—with each position holding one node at most.
- Lambda expressions can be used to simplify the definition of an event handler as an anonymous class that *implements* a functional interface, that is, an interface that requires only one method to be implemented.
- A lambda expression contains (1) a comma-separated list of parameters enclosed in parentheses—the data types of the parameters may be omitted, and the parentheses can

also be omitted if there is only one parameter; (2) the arrow token, ->; and (3) a method body, which can be a single expression or a block enclosed in curly braces. If the body of the method consists of a single expression, then the JVM evaluates the expression and returns its value. We can also use a return statement, but that requires curly braces.

- JavaFX includes many classes that allow us to animate a node on a scene. *FadeTransition*, *RotateTransition*, *TranslateTransition*, and *ScaleTransition* are examples of such classes.
- Each transition class typically provides methods to play the animation, set the number of types it repeats, play the animation in reverse, and execute some code after it finishes.
- A mouse activity generates a *MouseEvent*. A touch activity generates a *TouchEvent*.
- To handle a mouse or touch event, we implement the *EventHandler* interface and implement its *handle* method.
- The *getScene* method from the *Node* class allows us to get a reference to the *Scene* that a *Node* is in. The *getWindow* method from the *Scene* class allows us to get a reference to the *Stage* that the scene is in.
- JavaFX includes classes that make it easy to display various types of charts, including line charts, pie charts, and bar charts.
- The *ObservableList* interface is a list that can be linked to a GUI component that displays a list of values. Whenever the values in the list change, the GUI component is automatically updated to reflect those changes.
- *PieChart* and *BarChart* are examples of classes that can be bound to an *ObservableList*.

17.20 Exercises, Problems, and Projects

17.20.1 Multiple Choice Exercises

1. An example of a GUI component class is

   - *FXML*
   - *controller*
   - *TextField*
   - *Stage*

6. What are the primary uses of GUI components? (Check all that apply.)

   - Display information
   - Facilitate the coding of methods
   - Let the user control the program
   - Collect information from the user

11. In what package do you find the *Button*, *TextField*, and *ComboBox* classes?

    - *javafx.scene*
    - *javafx.scene.control*
    - *java.scene*
    - *java.awt*
    - *java.io*

17. V*Box* is a

    - Label
    - Layout container that arranges components vertically
    - Layout container that arranges components

horizontally
- Scene

22. The property of a *Label* element that specifies the text inside the label is

    - *Label*
    - *Word*
    - *Phrase*
    - *text*

27. The property that specifies the name of the Controller class for the View defined in the FXML document is

    - *control*
    - *fx:control*
    - *controller*
    - *fx:controller*

32. The property of a *Button* element that specifies the method called when the user clicks the button is

    - *action*
    - *press*
    - *onAction*
    - *onPress*

37. What attribute and annotation do we use with an instance variable of the Controller to reference a GUI component defined in an FXML document?

    - *id* and *FXML*
    - *id* and *@FXML*
    - *fx:id* and *FXML*
    - *fx:id* and *@FXML*

42. Assume that we have correctly defined the FXML attribute of a *Button* element that specifies the method to call when the user clicks on that button. What is the return type of that method?

    - *Button*
    - *void*
    - *boolean*
    - *onAction*

47. With JavaFX, a user interface must be defined using FXML; it cannot be defined programmatically.

    - True
    - False

50. We want to set up event handling programmatically when the user clicks on a button. What should the programmer do? (Check all that apply.)

    - Code a class that implements the *EventHandler<ActionEvent>* interface.
    - Declare and instantiate an object reference (a listener) of the class above.
    - Call the *handle* method.
    - Register the listener on the button.

55. Assuming everything has been coded correctly in the previous question, what happens when the user clicks a button?

    - The *handle* method executes.
    - The *Button* constructor executes.
    - The *start* method executes.

59. We want to build a class that implements an interface that

listens to key events. What interface should we implement?

- *EventHandler<ActionEvent>*
- *EventHandler<KeyEvent>*
- *EventHandler<MouseEvent>*
- *KeyHandler<Event>*

64. We are designing a GUI programmatically with three buttons; a different action will be taken depending on which button the user clicks. We want to code only one *private* class implementing the *EventHandler<ActionEvent>* interface. Inside the *handle* method, which method do we call to determine which button was clicked?

    - *getButton*
    - *getSource*
    - *getOrigin*

68. *NewLayout* is a layout container.

- True
- False

71. What is the maximum number of top-level controls that *a BorderPane* can manage?

    - 2
    - 3
    - 4
    - 5
    - 6

77. FXML elements can be nested.

    - True
    - False

80. Which one is not a transition class?

    - *FadeTransition*
    - *SequentialTransition*
    - *ParallelTransition*
    - *Scale*

85. What class encapsulates a touch event?

    - *Touch*
    - *TouchEvent*
    - *EventTouch*

89. What does the *getData* method of *XYChart.Series* return?

    - An *XYChart.Data* items
    - An *ObservableList* of *XYChart.Data* items
    - A *double*
    - A *Series*

17.20.2 Reading and Understanding Code

For Questions 21 to 25, consider the following FXML file representing the View for the application:

```
<?xml version="1.0" encoding="UTF-8"?>
<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>
<HBox fx:controller="MyController"
       xmlns:fx="http://javafx.com/fxml"
       alignment="center" spacing="10" >
  <Button fx:id="button1" text="Button 1"
          onAction="#go" />
  <Button fx:id="button2" text="Button 2"
          onAction="#go" />
  <Label fx:id="result" />
  <Button fx:id="button3" text="Button 3"
          onAction="#go" />
  <Button fx:id="button4" text="Button 4"
          onAction="#go" />
</HBox>
```

Description

1. How many buttons will be displayed in the window?
2. How are the buttons and the label organized in the window?
3. What class should we code in order to process clicks on the buttons by the user?
4. What method will execute when the user clicks on one of the buttons?
5. What is the return type of that method?

   For Questions 26 through 29, consider the following code (and assume that the FXML file defines the text for cb1, cb2, and cb3 as “Choice 1,” “Choice 2,” and “Choice 3”):

```
 /*  Controller class
 *   Anderson, Franceschi
 */
 import javafx.event.ActionEvent;
 import javafx.fxml.FXML;
 import javafx.scene.control.*;

 public class Controller
  {
   @FXML private CheckBox cb1;
   @FXML private CheckBox cb2;
   @FXML private CheckBox cb3;
   @FXML private Label label;
   private int read, write, execute;
   @FXML protected void mix( ActionEvent event )
    {
     CheckBox cb = ( CheckBox ) event.getSource( );
     if ( cb == cb1 )
       read = ( cb.isSelected( ) ? 4 : 0 );
     else if ( cb == cb2 )
       write = ( cb.isSelected( ) ? 2 : 0 );
     else if ( cb == cb3 )
       execute = ( cb.isSelected( ) ? 1 : 0 );
     int mode = read + write + execute;

     label.setText( "mode: " + mode );
  }
}
```

Description

6. What happens when the user checks “Choice 1” only?
7. What happens when the user checks “Choice 1” and then checks “Choice 2”?
8. What happens when the user checks “Choice 1,” then “Choice 2,” and then “Choice 3”?
9. What happens when the user checks “Choice 3,” then “Choice 2,” and then “Choice 2” again?

For Questions 30 through 32, consider the following code (and assume that the class extending *Application* exists and is correctly coded):

```
import javafx.event.*;
import javafx.scene.control.Button;
import javafx.scene.layout.*;
public class BoardView extends GridPane
{
  private Button [ ][ ] buttons;

  public BoardView( )
  {
    super( );

    ColumnConstraints col = new ColumnConstraints( );
    col.setPercentWidth( 25 );
    RowConstraints row = new RowConstraints( );
    row.setPercentHeight( 20 );

    for ( int i = 0; i < 5; i++ )
      getRowConstraints( ).add( row );
    for ( int j = 0; j < 4; j++ )
      getColumnConstraints( ).add( col );
    buttons = new Button[5][4];
    ButtonHandler bh = new ButtonHandler( );
    for ( int i = 0; i < 5; i++ )
    {
      for ( int j = 0; j < 4; j++ )
      {
        // instantiate the buttons
        buttons[i][j] = new Button( );
        buttons[i][j].setMaxWidth( Double.MAX_VALUE );
        buttons[i][j].setMaxHeight( Double.MAX_VALUE );
        add( buttons[i][j], j, i );
        buttons[i][j].setOnAction( bh );
      }
    }
  }
  private class ButtonHandler implements EventHandler<ActionEvent>
  {
    public void handle(  ActionEvent event )
    {
      for ( int i = 0; i < buttons.length; i++ )
        for ( int j = 0; j < buttons[i].length; j++ )
          if ( event.getSource( ) == buttons[i][j] )
          buttons[i][j].setText( "" + String.valueOf ( i + j ) );
  }
 }
}
```

Description

10. How many rows and columns are in the grid?

11. What happens when the user clicks on the *Button* located at the top left of the grid?

12. What happens when the user clicks on the *Button* located at the bottom right of the grid?

17.20.3 Fill In the Code

For Questions 33 through 35, consider the following FXML document representing a GUI:

```
<?xml version="1.0" encoding="UTF-8"?>

<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>

<BorderPane fx:controller="MyController"
            xmlns:fx="http://javafx.com/fxml"  >
  <top>
    <HBox alignment="center">
      <Button fx:id="button1" text="INSERT" />
    </HBox>
  </top>

  <left>
    <HBox alignment="center">
      <Button fx:id="button2" text="UPDATE" onAction="#go"/>
    </HBox>
  </left>

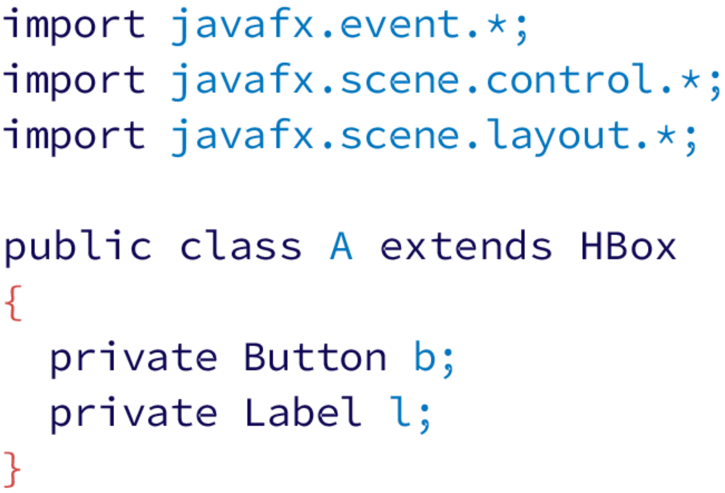
  <!-- answer to questions 33 to 35 go here -->

</BorderPane>
```

Description

1. Add a *VBox* element that contains a button at the *right* position within the *BorderPane*. The text of the button should say DELETE; when the user clicks on it, the *test* method of the *MyController* class should execute. The id of the button should be *button3*.
2. Add an *HBox* element that contains a label at the *center* position of the *BorderPane*. The text of the label should be SELECT. The id of the label should be *label1*.
3. Add a *VBox* element that contains a button at the bottom position within the *BorderPane*. The text of the button should be CREATE; when the user clicks on it, the *table* method of the *MyController* class should execute. The id of the button should be *button4.*

For Questions 36 through 40, consider the following class:



```
import javafx.event.*;
import javafx.scene.control.*;
import javafx.scene.layout.*;

public class A extends HBox
{
  private Button b;
  private Label l;
}
```

Description

1. Inside the constructor, this code instantiates the button *b* with the text “Button.”

```
// your code goes here
```

Description

2. Inside the constructor, this code instantiates the label *l* with the text “Hello.”

```
// your code goes here
```

Description

3. Inside the constructor, this code adds *b* and *l* to this *HBox* so that *b* is on the right and *l* is on the left:

```
// your code goes here
```

Description

4. Inside the constructor, this code registers the listener *mh*

on the button *b*:

```
// the MyHandler class is a private class implementing EventHandler
MyHandler mh = new MyHandler( );
// your code goes here
```

Description

5. Inside the *handle* method of a *private* inner class implementing the *EventHandler* interface, this code changes the text of *l* to “Button clicked” if the button *b* was clicked:

```
public void handle( ActionEvent ae )
{
 // your code goes here
}
```

Description

For Questions 41 through 46, consider the following class:

```
import javafx.scene.control.*;
import javafx.scene.layout.*;

public class B extends BorderPane
{
  private VBox left;
  private HBox top;
  private Button [ ] buttons; // length 4
  private TextField [ ] textfields; // length 3
  private Label label1;
  private Label label2;

}
```

Description

Also, assume that none of the instance variables have been instantiated and you are coding inside the constructor.

1. This code instantiates *top* and *left*.

```
// your code goes here
```

Description

2. This code instantiates the text fields with text *TF0*, *TF1*, and *TF2*, and it places them in that order inside *top*. They should fill the whole available width of *top*.

```
// your code goes here
```

Description

3. This code instantiates the buttons with text *Button 0, Button 1*, *Button 2*, and *Button 3*, and it places them in that order inside *left*. They should fill the whole available height of *left*.

```
// your code goes here
```

Description

4. This code adds *left* and *top* at the left and top positions of the *BorderPane*, respectively.

```
// your code goes here
```

Description

5. This code instantiates *labe11* and *label2* with the text *CENTER* and *BOTTOM*, respectively.

```
// your code goes here
```

Description

6. This code adds *label1* and *label2* at the center and bottom positions within the *BorderPane*, respectively.

```
// your code goes here
```

Description

7. Replace the anonymous class definition for a *Button* event handler with a lambda expression.

```
quit.setOnAction( new EventHandler<ActionEvent>( )
                 {
                   @Override
                   public void handle( ActionEvent event )
                   {
                     System.exit( 0 );
                   }
                 }
);
```

   Description

8. We have a reference named *myCanvas* to a *Canvas*. Define a rotation animation that will take place on *myCanvas* as follows: it should last 2.5 seconds, repeat five times, and go from a 45-degree angle to a 135-degree angle.
9. A sound file named *music.wav* is located in the current folder. Write code to play the sound three times in a row.
10. We have a reference named *myEvent* to a touch event that just happened. Retrieve and output the *x* and *y* coordinates of where the touch event happened.
11. We have already defined an *ArrayList* of *PieChart.Data* named *myList*. Create an *ObservableList* with it, and create a *PieChart* using that *ObservableList*.

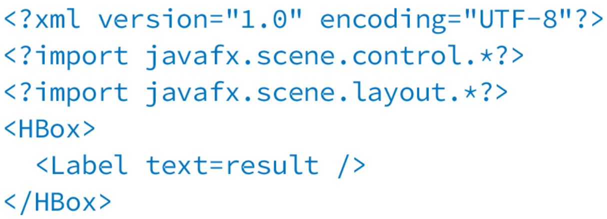
17.20.4 Identifying Errors in Code

1. Where is the error in this code sequence?

```
<?xml version="1.0" encoding="UTF-8"?>
<HBox xmlns:fx="http://javafx.com/fxml"
      alignment="center" spacing="10" >
  <Button text="Button 1" />
</HBox>
```

   Description

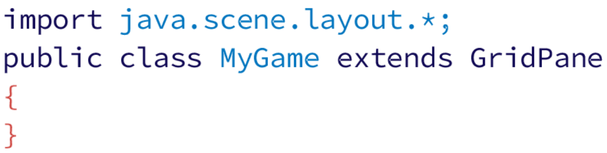
2. Where is the error in this code sequence?



```
<?xml version="1.0" encoding="UTF-8"?>
<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>
<HBox>
  <Label text=result />
</HBox>
```

Description

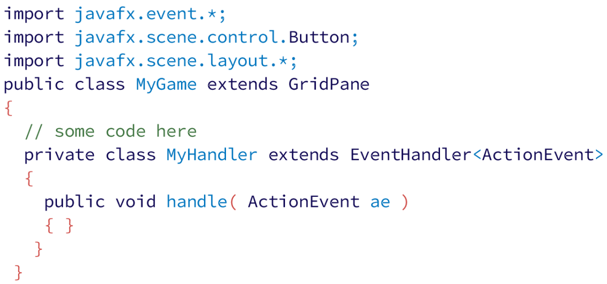
3. Where is the error in this code sequence?



```
import java.scene.layout.*;
public class MyGame extends GridPane
{
}
```

Description

4. Where is the error in this code sequence?



```
import javafx.event.*;
import javafx.scene.control.Button;
import javafx.scene.layout.*;
public class MyGame extends GridPane
{
  // some code here
  private class MyHandler extends EventHandler<ActionEvent>
  {
    public void handle( ActionEvent ae )
    { }
   }
 }
```

Description

5. Where is the error in this code sequence?

```
import javafx.event.*;
import javafx.scene.control.Button;
import javafx.scene.layout.*;
public class MyGame extends GridPane
{
  // some code here
  private class MyHandler implements EventHandler
  {
    public void handle( ActionEvent ae )
    { }
  }
}
```

Description

6. Where is the error in this code sequence?

```
XYChart.Series<String, Number> series
  = new XYChart.Series<String, Number>( );
series.add( new XYChart.Data<String, Number>( "HI", 2.0 ) );
```

Description

7. Where is the error in this code sequence?

```
// bc is a BarChart and has been instantiated
ArrayList<XYChart.Series<String, Number>> series
  = new ArrayList<XYChart.Series<String, Number>>( );
// fill in series here
bc.addAll( series );
```

Description

17.20.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. You coded the following class:

```
import java.net.URL;
import javafx.application.Application;
import javafx.fxml.FXMLLoader;
import javafx.scene.layout.VBox;
import javafx.scene.Scene;
import javafx.stage.Stage;

public class Test59 extends Application
{
  @Override
  public void start( Stage stage )
  {
    try
    {
      URL url = getClass( ).getResource( "fxml_ex1.fxml" );
      VBox root = FXMLLoader.load( url );
      Scene scene = new Scene ( root, 300, 275 );
      stage.setTitle( "Test" );
      stage.setScene( scene );
      stage.show( );
    }
    catch ( Exception e )
    {
      System.out.println( e.getMessage( ) );
    }
   }

  public static void main( String [ ] args )
  {
    launch( args );
  }
}
```

Description

The code compiles; when you run, the window does not open and you get the following message:

```
java.lang.NullPointerException: Location is required
```

Description

What do you think the problem is?

2. You coded the following FXML file, whose name is *fxml:ex60.fxml*:

```
<?xml version="1.0" encoding="UTF-8"?>
<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>
<VBox xmlns:fx="http://javafx.com/fxml"
       alignment="center" spacing="20" >

  <Label text=Welcome />
  <Label text="FXML Test" />
</VBox>
```

Description

Assume that the *Application* class is correctly coded. When you run, the window does not open and you get a LoadException with this message:

```
javafx.fxml.LoadException:
fxml:ex60.fxml:6
```

Description

Explain what the problem is and how to fix it.

3. You coded the following FXML file *(fxml_ex61.fxml*) and *Controller61* class:

```
<?xml version="1.0" encoding="UTF-8"?>

<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>

<VBox fx:controller="Controller61"
       xmlns:fx="http://javafx.com/fxml"
       alignment="center" spacing="10" >
  <Button fx:id="button" text="GO"
              onAction="#go" />
</VBox>
```

```
import javafx.event.ActionEvent;
import javafx.fxml.FXML;
import javafx.scene.control.*;

public class Controller61
{
  protected void go( ActionEvent event )
  {
    System.out.println( "Inside go" );
  }
}
```

Description

Assume that the *Application* class is correctly coded. The code compiles but when you run, the window does not open and you get a message starting with:

```
javafx.fxml.LoadException: Error resolving onAction='#go',
either the event handler is not in the Namespace or there is
an error in the script
```

Description

Explain what the problem is and how to fix it.

4. You coded the following in the file *Test62.java*:

```
import javafx.application.Application;
import javafx.scene.Scene;
import javafx.stage.Stage;
public class Test62 extends Application
{
 public void start( Stage stage )
 {
  Ex62 root = new Ex62( );
  Scene scene = new Scene( root, 300, 275 );
  stage.setTitle( "Test" );
  stage.setScene( scene );
 }
 public static void main( String [ ] args )
 {
  launch( args );
 }
}
```

Description

Assume that the *Ex62* class is correctly coded. The code compiles and runs, but the window does not show. Explain what the problem is and how to fix it.

5. You coded the following in the *Ex63.java* file:

```
import javafx.scene.control.*;
import javafx.scene.layout.*;
import javafx.event.*;
public class Ex63 extends VBox
{
  private Button button;
  private Label label;

  public Ex63( )
  {
    super( );
    label = new Label( "HI" );
    button = new Button( "GO" );
    getChildren( ).add( label );
    getChildren( ).add( button );
  }
  private class ButtonHandler implements EventHandler<ActionEvent>
  {
    public void handle( ActionEvent ae )
    {
      label.setText( "Hello" );
    }
  }
}
```

Description

Assume that the *Application* class has been correctly coded. The code compiles and runs. However, when you click the button, the text in the label does not change. Explain what the problem is and how to fix it.

17.20.6 Write a Short Program

1. Write a program that displays a text field and two buttons labeled “uppercase” and “lowercase.” When the user clicks on the uppercase button, the text changes to uppercase; when the user clicks on the lowercase button, the text changes to lowercase. Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.
2. Write a program with two radio buttons and a text field. When the user clicks on one radio button, the text changes to lowercase; when the user clicks on the other radio button, the text changes to uppercase. Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.
3. Same as 65, except create the GUI programmatically, not using FXML.
4. Write a program with three checkboxes that allows a user to select toppings for a pizza order: extra cheese, sausage, and anchovies. As the user selects/deselects each checkbox, display the current order in a label.
5. Write a program that simulates a multiple choice question of your choice; the question should be a “check all that apply” type of question. There should be at least four possible answers, each using a checkbox. When the user selects any checkbox, your program should process the user’s answer and show whether the answer is true (all checkbox selections are correct) or false (at least one

checkbox selection is incorrect) in a label. Use FXML for the GUI and to set up event handling; include a Model.

6. Same as 68, but include a button to process the answer; do not process the answer when the user selects checkboxes.
7. Write a program that simulates a guessing game in a GUI program. Ask the user for a number between 1 and 6 in a text field, and then roll a die randomly and indicate whether or not the user won. Write the program in such a way that any invalid user input (i.e., not an integer between 1 and 6) is rejected and the user is asked again for input. Use FXML for the layout but generate and handle the checkboxes programmatically; include a Model. Be sure that the initial state of the View matches the initial state of the Model.
8. Write a program that simulates a guessing game in a GUI program. Generate a secret random number between 1 and 100; that number is hidden from the user. Ask the user to guess a number between 1 and 100 in a text field, and then tell the user whether the number is too high, too low, or is the correct number. Let the user continue to guess until the correct number is guessed. Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.
9. Modify the *ComboBox* example in this chapter to use *ListView* instead.

10. Write a program that displays a 4-by-6 grid of buttons, each with some unique text. One button is the “winning” button, which your model determines randomly. When the user clicks on the winning button, change its text to “Won.” If the user clicks on any other button, change its text to “No.” Use code for the GUI and to set up event handling; include a Model.
11. Same as Exercise 73 with the following additions: Keep track of how many times the user clicks on buttons. If the user has not won after five clicks, the text on the last button clicked should be changed to “Lost.” Once the user has lost or won, you should disable the game; that is, the buttons should no longer respond to clicks from the user.
12. Write a program that displays a combo box and a label. The combo box displays five U.S. states using two letters for each state (e.g., CA, MD). When the user selects a state from the combo box, the label is populated with the

full name of the state (e.g., if the user selects MD, the label is populated with Maryland). Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

13. Same as 75, except use code for the GUI instead of FXML.
14. Write a program that counts and displays how many times the user touches the screen and plays a short sound every time the user touches the screen. The count should be displayed and incremented each time the user touches the screen.
15. Write a program that plays the same greeting in three languages. Provide a button for each language. When the user presses a button, play the greeting in that language. Use code for the GUI and use lambda expressions to define the listener for each button.
16. Write a program that shows a ball bouncing on the ground. When the user touches the screen, the ball drops and bounces on the ground. The touch event should be disabled after that. The ball bounces down and up five times; each time it bounces up, it travels half the previous distance.
17. Write a program that shows a ball at the center of a *BorderPane*. Include a button at the bottom of the *BorderPane*. When the user clicks on the button, animate the ball so that it travels in a square. Disable the button while the animation is running and enable the button when the animation stops.

17.20.7 Programming Projects

1. Write a GUI-based tic-tac-toe game for two players. Use

code for the GUI and to set up event handling; include a Model.

2. Write a GUI-based program that analyzes a word. The user will type the word in a text field. Provide buttons for the following:

   - One button, when clicked, displays the length of the word.
   - Another button, when clicked, displays the number of vowels in the word.
   - Another button, when clicked, displays the number of uppercase letters in the word.

   Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

6. Write a GUI-based program that analyzes a soccer game. The user will type the names of two teams and the score of the game in four text fields. You should add appropriate labels and create buttons for the following:

   - One button, when clicked, displays which team won the game.
   - Another button, when clicked, displays the game score.
   - Another button, when clicked, displays by how many goals the winning team won.

   Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

10. Same as 83, except use code for the GUI, not FXML.

11. Write a GUI-based program that analyzes a round of golf. You will retrieve the data for 18 holes from a text file. Each line in the file will include the par for that hole (3, 4, or 5)

and your score for that hole. Your program should read the file and display a combo box listing the 18 holes. When the user selects a hole, the score for that hole should be displayed in a label. Provide buttons for the following:

- One button, when clicked, displays whether your overall score was over par, under par, or par.
- Another button, when clicked, displays the number of holes for which you made par.
- Another button, when clicked, displays how many birdies you scored. (A birdie on a hole is 1 under par.)

Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

15. Same as 85, except use code for the GUI, not FXML.
16. Write a GUI-based program that analyzes statistics for tennis players. You will retrieve the data from a text file. Each line in the file will list the name of a player, the player’s number of wins for the year, and the player’s number of losses for the year. Your program should read the file and display the list of players. When the user selects a player, the winning percentage of the player should be displayed in a label. Provide buttons for the scenarios that follow:

    - One button, when clicked, displays which player had the most wins for the year.
    - Another button, when clicked, displays which player had the highest winning percentage for the year.
    - Another button, when clicked, displays how many players had a winning record for the year.

    Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

20. Write a GUI-based program that simulates the selection of a basketball team. You will retrieve the data from a text file containing 10 lines. Each line will list the name of a player. Your program needs to read the file and display 10 checkboxes representing the 10 players. A text area will display the team, made up of the players being selected. A basketball team has five players. Your program should not allow the user to change his or her selection after the team has five players. Every time the user checks or unchecks a checkbox, the team in the text area should be updated accordingly. Provide buttons for the following:

    - One button, when clicked, displays how many players are currently on the team.
    - Another button, when clicked, displays how many players remain unselected.

    Use code for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

23. Write a GUI-based program that enables the user to choose a file containing an image. Your application then displays that image in a label. Your GUI should include a button and a label. When the user clicks on the button, open a file-choosing dialog box to enable the user to select a file. (Hint: look up the *FileChooser* class in the Java Class Library.) The dialog box should show the files in the current directory with an extension of either *jpg* or *gif*.

Use FXML for the GUI and to set up event handling; include a Model.

24. Write a GUI-based program that displays a team on a soccer field. You will retrieve data from a text file containing 11 lines. Each line will contain the name of a player. Your program should read the file and display the following window when it starts. (You can assume that the players in the file are not in any particular order.) Each cell is a button; when the user clicks on a button, the button replaces its text with the name of the player.

Left wing (11)	Striker (9)	Right wing (7)	
Left midfielder (6)	Midfielder (10)	Right midfielder (8)	
Left defender (3)	Stopper (4)	Sweeper (5)	Right defender (2)
	Goalie (1)		

Use FXML for the GUI and to set up event handling; include a Model.

25. Write a program that displays a color on canvas and allows

the user to change the color by changing its red, green, and blue components. Provide three sliders, with each slider representing a coefficient between 0 and 1 for the red, green, and blue amount, respectively. As the user manipulates each slider, change the color displayed on the canvas. Hint: use the *fillRect* method to create a rectangle the same size as the canvas.

Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

26. Same as 91, but create the GUI programmatically instead.
27. Write a GUI-based program that includes three sliders and a label. The sliders are used to define the red, green, and blue components of a color that you should use for the background color of the label. Each slider represents a coefficient between 0 and 255 for the red, green, and blue amount, respectively. As the user moves a slider, the background color of the label changes.

    Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.
28. Same as 93, but create the GUI programmatically instead.
29. Write a GUI-based program that generates a UNIX permission command; the UNIX permission command format is:

    ```
    chmod xyz filename
    ```

    Description

    where *x*, *y,* and *z* have values between 0 and 7.

    Provide the following:

    - Three combo boxes for the permission level for all, the group, and the owner of a file. In each combo box, the

  user can choose the permission level, a number between 0 and 7.
- One text field, where the user enters the name of a file.
- A label that displays the permission command for that file based on the values of the three combo boxes. Every time the user interacts with one of the combo boxes, the label should be updated.

Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

33. Same as 95, except that you should update the label every time the user updates the name of the file.
34. Same as 95, but create the GUI programmatically instead of with FXML.
35. Write a GUI-based program that simulates entering the destination in a car's GPS system. The user can enter a destination by typing it in a text field or by choosing a destination from a drop-down list of previous destinations. The list of previous destinations is sorted as follows: the most recent destination is at the top and the least recent is at the bottom of the list. If the user enters a destination in a text field, the user needs to click a button to validate it. A label displays the destination selected. When a destination is either entered or selected by the user, the list of previous destinations should be updated; the current destination goes to the top of the list. There should not be any duplicate destinations in the list. In this version, the list is empty when we start the program. Data are not persistent: Every time we start the program, the list of previous destinations is empty.

    Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

36. Same as 98, but the list of previous destinations should be persistent. It can be stored in a file and the drop-down list can be populated by the contents of the file.
37. Write a program that manages and displays a list of your friends' names and phone numbers. The list of names and phone numbers is displayed in a *ListView* component. Your program should allow the user to add and delete names and phone numbers one at a time. Furthermore, the data should be persistent and stored in a file. When the program starts, the contents of the file are displayed in the *ListView*. Every time a name and phone number are added or deleted, the file should be updated.

38. Write a drawing program. A *BorderPane* divides the screen into two parts: on the right, the drawing takes place. On the left are four buttons that enable the user to change the drawing color to any of three colors and to clear the drawing on the right side of the screen. The user draws by

touching and moving his or her finger on the screen. The drawing is made with the selected color.

39. Write a program that displays a pie chart on the left and its equivalent bar chart on the right. Both charts are dynamic and reflect four values that are input by the user at the bottom of the screen. You can use default values when the program starts.

17.20.8 Technical Writing

1. You are part of a team writing a complex program that includes a GUI. Our team is made up of programmers, as well as one artist and one HTML/XML developer who do not know programming but could learn some basic things quickly. We know that the GUI uses many different components and does not lend itself to using simple data structures like arrays. We know that the GUI is well defined and that the initial data in all its components are always the same. Would you define the GUI with FXML or programmatically? Discuss the pros and cons.

17.20.9 Group Project (for a group of 1, 2, or 3 students)

1. Design and code a program that simulates an auction. You should consider the following:
   A file contains a list of items to be auctioned. You can decide on the format of this file and its contents. For example, the file could look like this:

   ```
   Oldsmobile,oldsmobile.gif,100
   World Cup soccer ticket,soccerTickets.gif,50
   Trip for 2 to Rome,trip.gif,100
   ```

   Description

In the preceding file sample, each line represents an item as follows: The first field is the item’s description, the second field is the name of a file containing an image of the item, and the third field is the minimum bid. You can assume that each item’s description is unique.

Items are offered via an online-like auction. (You do not need to include any network programming; your program is a single-computer program.) Users of the program can choose which item to bid on from a list or combo box. Along with displaying the description of the item, your program should show a picture of the item and the current highest bid. (At the beginning, the current highest bid is the minimum bid.) Users bid on an item by selecting the item, typing a name (you can assume a different name), and entering a price for the item. Each time a bid is made, the item’s highest bid, displayed on the screen, should be updated if necessary.

Use FXML for the GUI and to set up event handling; include a Model. Be sure that the initial state of the View matches the initial state of the Model.

Appendix B

Operator Precedence

These rules of operator precedence are followed when expressions are evaluated. Operators in a higher level in the hierarchy—defined by their row position in the table—are evaluated before operators in a lower level. Thus, an expression in parentheses is evaluated before a shortcut postincrement is performed, and so on with the operators in each level. When two or more operators on the same level appear in an expression, the evaluation of the expression follows the corresponding rule for same-statement evaluation shown in the second column.

Operators	**Order of Same-Statement Evaluation**	**Operation**
( )	left to right	parentheses for explicit grouping
++—	right to left	shortcut postincrement and postdecrement
++— !	right to left	shortcut preincrement and predecrement, logical unary NOT
* / %	left to right	multiplication, division, modulus
+ -	left to right	addition or *String* concatenation, subtraction
< <= > >= instanceof	left to right	relational operators: less than, less than or equal to, greater than, greater than or equal

		to; instanceof
== !=	left to right	equality operators: equal to and not equal to
&&	left to right	logical AND
||	left to right	logical OR
?:	left to right	conditional operator
= += −= *= /= %=	right to left	assignment operator and shortcut assignment operators

Appendix C

The Unicode Character Set

Java characters are encoded using the Unicode Character Set, which is designed to support international alphabets, punctuation, and mathematical and technical symbols. Each character is stored as 16 bits, so as many as 65,536 characters are supported.

The American Standard Code for Information Interchange (ASCII) character set is supported by the first 128 Unicode characters from 0000 to 007F, which are called the controls and Basic Latin characters, as shown on the next page.

Any character from the Unicode set can be specified as a *char* literal in a Java program by using the following syntax: '\uNNNN' where NNNN are the four hexadecimal digits that specify the Unicode encoding for the character.

For more information on the Unicode character set, visit the Unicode Consortium's website: *www.unicode.org*.

Appendix D

Representing Negative Integers

The industry standard method for representing negative integers is called **two’s complement**. Here is how it works:

For an integer represented using 16 bits, the leftmost bit is reserved for the sign bit. If the sign bit is 0, then the integer is positive; if the sign bit is 1, then the integer is negative.

For example, let’s consider two numbers, one positive and one negative.

Description

Using the methodology presented in the text for converting a binary number to a decimal number, we can convert the binary number, *a*, to its decimal equivalent. Hence, the value of *a* is calculated as follows:

Description

In contrast, *b*, the negative number, is represented in binary using the two’s complement method. The leftmost bit, which is the sign bit, is a 1, indicating that *b* is negative. To calculate the value of a negative number, we first calculate its two’s complement. The two’s complement of any binary number is another binary number, which, when added to the original number, will yield a sum consisting of all 0s and a carry bit of 1 at the end.

To calculate the two's complement of a binary number, *n*, subtract *n* from 2^d, where *d* is the number of binary digits in *n*. The following formula summarizes that rule:

Description

Knowing that $2^d - 1$ is always a binary number containing all 1s, we can simplify our calculations by first subtracting 1 from 2^d, then adding a 1 at the end.

Description

So to calculate the two's complement of *b*, which has 16 digits, we subtract *b* from a binary number consisting of 16 1s, then add 1, as shown here.

Description

Thus, the two's complement of *b*, which we will call *c*, is 0000 0000 0010 0110.

Another, simpler, way to calculate a two's complement is to invert each bit, then add 1. Inverting bits means to change all 0s to 1s and to change all 1s to 0s. Using this method, we get

Description

We can verify that the two's complement of *b* is correct by calculating the sum of *b* and *c*.

Description

Converting *c* to decimal will give us the value of our original number *b*, which, as we remember, is negative. We have

Description

Because a leftmost bit of 0 indicates that the number is positive, using 16 bits, the largest positive number (we will call it *max*) that we can represent is

Description

This is equivalent to $2^{15} - 1$, which is 32,768 – 1, or 32,767.

Using 16 bits, then, the smallest negative number (we will call it *min*) that we can represent is

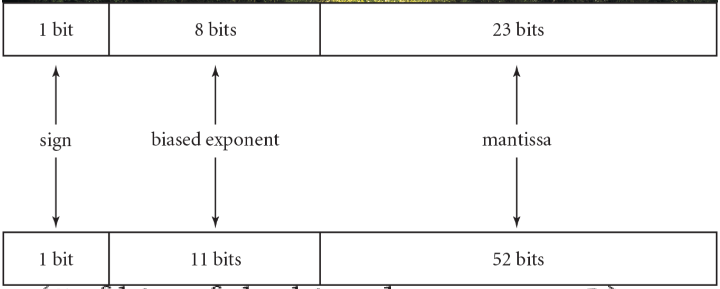
`1000 0000 0000 0000`

The two's complement of *min* is *min* itself. If we invert the bits and add 1, we get the same value we started with:

Description

and therefore *min* is -2^{15} or –32,768.

Thus, using 16 bits, we can represent integers between –32,768 and 32,767.



1 bit
8 bits
23 bits
sign
biased exponent
mantissa
1 bit
11 bits
52 bits

$$2^{(\#\text{ of bits of the biased exponent}-1)}-1$$

$$2^{(8-1)}-1=2^{7}-1=127$$

Real exponent	-127	-126	...	0	...	127	128
+Bias	127	127	...	127	...	127	127
Biased exponent	0	1	...	127	...	254	255

$$2^{(11-1)}-1=2^{10}-1=1023$$

$$(-1)^{\text{sign}}*(1+\text{significand})*2^{(\text{biased exponent}-\text{bias})}$$

$$=2^{7}+2^{2}+2^{1}+2^{0}$$

$$=128+4+2+1$$

$$=135$$

$$=(-1)^{0}*(1+.1101)*2^{(135-127)}$$

$$=1.1101*2^{8}$$

$$=11101\ 0000$$

$$= 2^8 + 2^7 + 2^6 + 2^4$$

$$= 256 + 128 + 64 + 16$$

$$= 464$$

$$= 1.1101 * 2^8$$

$$= (1 + 1 * \frac{1}{2}1 + 1 * \frac{1}{2}2 + 0 * \frac{1}{2}3 + 1 * \frac{1}{2}4) * 2^8$$

$$= (1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{16}) * 2^8$$

$$= (1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{16}) * 256$$

$$= 464$$

$$5 = 101$$

$$.375 = .25 + .125$$

$$= \frac{1}{4} + \frac{1}{8}$$

$$= \frac{1}{2}2 + \frac{1}{2}3$$

$$= 0 * \frac{1}{2}1 + 1 * \frac{1}{2}2 + 1 * \frac{1}{2}3$$

$$y = -101.11$$

$$= -1.01011 * 2^2$$

$$\text{Biased exponent} = 2 + 127$$

$$= 129$$

$$129 = 1000\ 0001$$

Representing Floating-Point Numbers

IEEE 754, a specification accepted worldwide and used by the Java language, defines how to represent floating-point numbers in binary numbers. Single-precision floating-point numbers use 32 bits of memory, and double-precision floating-point numbers use 64 bits.
Here is how single- and double-precision floating-point numbers are represented:

Description

The leftmost bit stores the sign of the floating-point number; a 0 indicates a positive number, while a 1 indicates a negative number.
To represent the exponent of the number, which can be positive or negative, each representation stores a positive, biased exponent, calculated by adding a fixed bias, or scaling factor, to the real exponent of the number. The purpose of the bias is to be able to represent both extremely large and extremely small numbers. The bias is equal to

Description

Thus, for single precision, the bias is

Description

In single-precision, the 8-bit biased exponent can store 256 positive values (0 to 255). Thus, with a bias of 127, we can represent floating-point numbers with real exponents from –127 to 128, as shown here:

Description

Conversely, to find the real exponent from the biased exponent, we subtract the bias. For example, if the biased exponent is 150, then the real exponent is 150 − 127, which is 23. Similarly, if the biased exponent is 3, the actual exponent is 3 − 127, which is −124.

For double precision, the bias is

Description

A floating-point number is considered to be in the form

Description

By definition, the significand is of the form 0 followed by a dot followed by a string of 0s and 1s, for example, 0.1101. That string of 0s and 1s is known as the mantissa.

For example, if the significand is 0.1101, then the mantissa is 110100…0

As an example, let’s convert a single-precision binary number to a decimal floating-point number. We will convert the following single-precision IEEE 754 floating-point number:

0	10000111	11010000 … 0

The leftmost digit, 0, tells us that the number is positive. The biased exponent is 10000111, which converted to decimal, is

Description

The bias for single-precision floating-point numbers is 127, so the number is

Description

In decimal, the number is

Description

Given that .1 is ½1 or ½ in decimal, and .01 is ½2 or ¼, and .0001 is ½4 or 1/16 in decimal, we also could have calculated the number using this method:

Description

Now, let’s convert a decimal floating-point number into single-precision, binary format. Here, we will convert the number –5.375, which we’ll call *y*. First, without dealing with the sign yet, we convert the whole number portion (5) to binary, getting 101:

Description

Then we convert the fractional part to binary:

Description

Thus, .375 as represented in binary is .011.
Therefore, y can be represented in binary as

Description

We now can deduce the sign, the biased exponent, and the mantissa. The sign is 1 because the number is negative. The significand is 1.01011, and therefore the mantissa is 01011000…00. The exponent is 2, so the biased exponent is 129 (2 plus the bias for single-precision numbers, which is 127):

Description

Converting 129 to binary, we get

Description

Therefore, the IEEE 754 single-precision value of the number *y* is

1	10000001	010110000…0

Appendix F

Solutions to Selected Exercises

1.7 Exercises, Problems, and Projects

1.7.1 Multiple Choice Exercises

1. Java
2. servers.
3. is a multiple of 4.
4. C
5. *javac Hello.java*

1.7.2 Converting Numbers

1. 0110 0001 1100
2. 0x15

1.7.3 General Questions

1. 3 billion
2. red = 51; green = 171; blue = 18
3. *javac*

2.6 Exercises, Problems, and Projects

2.6.1 Multiple Choice Exercises

1.    ```
   int a;
   ```

2.6.2 Reading and Understanding Code

1. 12.5
2. 2.0
3. 4
4. 5
5. 2.4
6. 5
7. 0

2.6.3 Fill In the Code

1.    ```
   boolean a;
   a = false;
   ```

2.
   ```
   double avg = (double) ( a + b ) / 2;
   System.out.println( "The average is " + avg );
   ```
3.    ```
   a *= 3;
   ```

2.6.4 Identifying Errors in Code

1. Cannot assign a *double* to a *float* variable (possible loss of precision).
2. There should not be a space between – and =.

2.6.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. Cannot assign a *double* to an *int* variable (possible loss of precision). Change to:
   ```
   int a = 26;
   ```
2. =+ is different from += (shortcut operator). Here, *a* is assigned the value + 3. To add 3 to *a*, change the second statement to:
   ```
   a += 3;
   ```

3.18 Exercises, Problems, and Projects

3.18.1 Multiple Choice Exercises

1. `import`
2. `new`
3. It is a class method.
4. `double`
5. `Math.E;`

3.18.2 Reading and Understanding Code

1. hello
2. 3.141592653589793
3. 8

3.18.3 Fill In the Code

1. `System.out.println( s.length( ) );`

```
   System.out.print( "Welcome " );
   System.out.print( "to " );
   System.out.print( "Java " );
2. System.out.print( "Illuminated\n" );
   // code below assumes we have imported Scanner
   Scanner scan = new Scanner( System.in );
   System.out.print( "Enter two integers > " );
   int i = scan.nextInt( );
   int j = scan.nextInt( );
   int min = Math.min( i, j );
3. System.out.println( "min of " + i + " and " + j + " is " + min );
   // code below assumes we have imported Scanner
   Scanner scan = new Scanner( System.in );
   System.out.print( "Enter a double > " );
   double number = scan.nextDouble( );
   double square = Math.pow( number, 2 );
4. System.out.println( number + " squared = " + square );
```

3.18.4 Identifying Errors in Code

1. The *System* class begins with a capital S. It should be *System*, not system.
2. The *round* method of the *Math* class returns a *long*; a *long* cannot be assigned to a *short* variable due to a potential loss of precision.
3. The char *‘H’* cannot be assigned to the *String s*. The two data types are not compatible.

3.18.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. Java is case sensitive. The *Math* class needs to be spelled with an uppercase M.
2. In the output statement, we are just printing the value of *grade* without any formatting. To format *grade* as a percentage, the output statement should be:

```
System.out.println( "Your grade is " + percent.format( grade ) );
```

4.7 Exercises, Problems, and Projects

4.7.1 Multiple Choice Exercises

1. *javafx.scene.canvas*
2. true
3. the (*x, y*) coordinate of the upper-left corner of the rectangle we are drawing
4. 256

4.7.2 Reading and Understanding Code

1. 250 pixels

4.7.3 Fill In the Code

1.
   ```
   gc.setFill( Color.RED );
   gc.setStroke( Color.GREEN );
   ```

2.
   ```
   gc.fillRect( 50, 30, 50, 270 );
   ```

4.7.4 Identifying Errors in Code

1. There should be double quotes around the literal *Find a bug*, not single quotes. Single quotes are used for a *char*, not a *String*.
2. There is no *public color* instance variable in the *GraphicsContext* class. The *setFill* or *setStroke* method should be used to set the current color.

4.7.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. The rectangle is being drawn outside the bounds of the window. The largest visible x coordinate is 699.

5.14 Exercises, Problems, and Projects

5.14.1 Multiple Choice Exercises

☐ `a < b` `true`

☐ `a != b` `true`

☐ `a == 4` `false`

☐ `( b - a ) <= 1` `false`

☐ `Math.abs( a - b ) >= 2` `true`

☐ `( b % 2 == 1 )` `true`

1. ☐ `b <= 5` `true`
2. yes

☐ `a < b || b < 10` `no`

☐ `a != b && b < 10` `yes`

☐ `a == 4 || b < 10` `yes`

3. ☐ `a > b && b < 10` `no`

5.14.2 Reading and Understanding Code

1. *true*
2. 27 is divisible by 3
   End of sequence
3. Hello 3
   Hello 4
   Done
4. letter 2

5.14.3 Fill In the Code

1. 
```
if ( a )
   a = false;
else
   a = true;
```

2. 
```
if ( b % c == 0 )
   a = true;
else
   a = false;
```

3. 
```
if ( a && b > 10 )
   c++;
```

5.14.4 Identifying Errors in Code

1. The && operator cannot be applied to two *int* operands (*a1* and *a2*).
2. We need a set of parentheses around *b1*.
3. There is no syntax error.

5.14.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. The expression `a = 31` evaluates to an *int*, 31. The *if* condition requires a *boolean* expression. To fix the problem, replace `a = 31` with `a == 31`.

6.14 Exercises, Problems, and Projects

6.14.1 Multiple Choice Exercises

1. The code runs forever.
2. true

6.14.2 Reading and Understanding Code

1. Enter an int > 3
   Enter an int > 5
   Hello
   Enter an int > –1
   Hello
2. *i* is 8 and *product* is 42
3. 3
4. *i* is 40 and *sum* is 60
5. 3
   3
   3
   3
   4

6.14.3 Fill In the Code

```
   System.out.print( "Enter an integer > " );
   int value = scan.nextInt( );
   while ( value != 20 )
   {
     if ( value >= start )
       System.out.println( value );
     System.out.print( "Enter an integer > " );
     value = scan.nextInt( );
1. }
   Scanner scan = new Scanner( System.in );
   System.out.print( "Enter a word > " );
   word = scan.next( );
   while ( ! word.equals( "end" ) )
   {
     sentence += word + " ";
     System.out.print( "Enter a word > " );
     word = scan.next( );
2. }
   Scanner scan = new Scanner( System.in );
   int sum = 0;
   System.out.println( "Enter an integer > " );
   int value = scan.nextInt( );
   while ( value != 0 && value != 100 )
   {
     sum += value;
     System.out.println( "Enter an integer > " );
     value = scan.nextInt( );
   }
3. System.out.println( "sum is " + sum );
```

6.14.4 Identifying Errors in Code

1. The variable *num* needs to be initialized after it is declared, and a priming read is needed.
2. The loop is infinite; *number* is always different from 5 or different from 7. The logical OR (`||`) should be changed to a logical AND (`&&`).

6.14.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. It is an infinite loop; *i* should be incremented, not decremented, inside the body of the *while* loop so that the loop eventually terminates.
2. In the *for* loop header, the loop initialization statement, the loop condition, and the loop update statement should be separated by semicolons (;), not commas(,).

7.19 Exercises, Problems, and Projects

7.19.1 Multiple Choice Exercises

1. The convention is to start with an uppercase letter.
2. true
3. can be basic data types, existing Java types, or user-defined types (from user-defined classes).
4. one parameter, of the same type as the corresponding field.
5. these fields do not need to be passed as parameters to the methods because the class methods have direct access to them.
6. All of the above.

7.19.2 Reading and Understanding Code

1. *double*
2. an instance method (keyword *static* not used)
3. `public static void foo3( double d )`

7.19.3 Fill In the Code

1.
   ```
   private int grade;
   private char letterGrade;
   ```
2.
   ```
   public TelevisionChannel( String newName, int newNumber,
                             boolean newCable )
   {
     name = newName;
     number = newNumber;
     cable = newCable;
   }
   ```
3.
   ```
   public String toString( )
   {
     return ( "name: " + name + "\tnumber: "
              + number + "\tcable: " + cable );
   }
   ```
4.
   ```
   public String typeOfChannel( )
   {
     if ( cable )
       return "cable";
     else
       return "network";
   }
   ```

7.19.4 Identifying Errors in Code

1. The *toString* method needs to return a *String*, not output data.
2. The method header is incorrect; it should be
   ```
   public double calcTax( )
   ```
3. There are two errors: The assignment operator = should not be used when declaring an *enum* set. And the *enum* constant objects should not be *String* literals but identifiers. The statement should be:
   ```
   enum Months { January, February, March };
   ```

7.19.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. The compiler understands that *Grade* is a method since its header says it returns a *char*. It looks as if it is intended to be a constructor so the keyword *char* should be deleted from the constructor header.
2. The constructor assigns the parameter *numberGrade* to itself, therefore not changing the value of the instance variable *numberGrade*, which by default is 0. The constructor could be recoded as follows:

```
public Grade( int newGrade )
{
  numberGrade = newGrade;
}
```

8.11 Exercises, Problems, and Projects

8.11.1 Multiple Choice Exercises:

1. `int [ ] a;` and `int a[ ];`
2. 0
3. `a.length`
4. false

8.11.2 Reading and Understanding Code

1. 48.3
2. 12

48
65

3. 14
4. It counts and returns how many elements in the argument array have the value 5.
5. It returns an array of *Strings* identical to the argument array except that the *Strings* are all in lowercase.

8.11.3 Fill In the Code

1.
```
if ( a[i] > 20 )
  System.out.println( a[i] );
```
2.
```
System.out.println( "a[" + i + "] = " + a[i] );
```
3.
```
if ( a.length < 2 )
  return false;
else if ( a[0].equals( a[1] ) )
  return true;
else
  return false;
```

8.11.4 Identifying Errors in Code

1. Index –1 is out of bounds; the statement `System.out.println( a[-1] );` will generate an *ArrayIndexOutOfBoundsException* at run time.
2. When declaring an array, the square brackets should be empty. Replace `a[3]` with `a[ ]`.
3. Although the code compiles, it outputs the hash code of the array a. To output the elements of the array, we need to loop through the array elements and output them one by one.

8.11.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. Index `a.length` is out of bounds; when i is equal to `a.length`, the expression `a[i]` will generate a run-time exception. Replace <= with < in the loop condition.

9.11 Exercises, Problems, and Projects

9.11.1 Multiple Choice Exercises

1. `int[ ][ ] a;` and `int a[ ][ ];`
2. false
3. `a[2].length`
4. true
5. *java.util*

9.11.2 Reading and Understanding Code

1. 3
2. Munich
   Stuttgart
   Berlin
   Bonn
3. Munich
   Berlin
   Ottawa
4. It counts and returns the number of elements in the parameter array *a*.

5. It returns an *int* array of the same length as the length of the parameter array *a*. Each element of the returned array stores the number of columns of the corresponding row in *a*.
6. 7 (at index 0) 45 (at index 1) 21 (at index 2)

9.11.3 Fill In the Code

1.
```
System.out.println( geo[0][5] );
for ( int i = 0; i < geo.length; i++ )
{
  for ( int j = 0; j < geo[i].length; j++ )
       System.out.println( geo[i][j] );
```
2.
```
}
int count = 0;
for ( int j = 0; j < a[1].length; j++ )
{
  if ( a[1][j] == 6 )
       count++;
}
```
3.
```
System.out.println( "# of 6s in the 2nd row: " + count );
```
4. This method returns the product of all the elements in an array.
```
public static int foo( int [ ][ ] a )
{
  int product = 1;
  for ( int i = 0; i < a.length; i++ )
  {
    for ( int j = 0; j < a[i].length; j++ )
    {
      product *= a[i][j];
    }
  }
  return product;
}
```
5.
```
System.out.println( languages.size( ) );
```

```
for ( String s : languages )
{
  if ( s.charAt( 0 ) == 'P' )
    System.out.println( s );
```

6. `}`

9.11.4 Identifying Errors in Code

1. Array dimension missing in `new double [ ][10]`

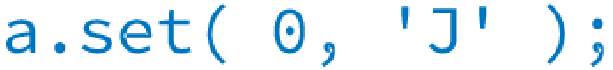
   Example of correct code: `double [ ][ ] a = new double [4][10];`
2. Cannot declare an *ArrayList* of a primitive data type; the type needs to be a class (for example: *Double*)
3. Correct syntax is `variable = expression`. Because `a.size( )` is not a variable, we cannot assign a value to it.

9.11.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. Other than `a[0][0]`, the first row is not taken into account because *i* is initialized to 1 in the outer loop. It should be `int i = 0;` not `int i = 1`.
2. Index 3 is out of bounds. There are only 3 elements in *a*; the last index is 2.
3. Because *ArrayList* elements begin at index 0, the statement

   ```
   a.set( 1, 'J' );
   ```

   sets the value of the second element of the *ArrayList*. To set the value of the first element, use this statement:



```
a.set( 0, 'J' );
```

10.10 Exercises, Problems, and Projects

10.10.1 Multiple Choice Exercises

1. a class inheriting from another class.
2. *protected* and *public* instance variables and methods
3. You cannot instantiate an object from an *abstract* class.
4. the class must be declared *abstract*.

10.10.2 Reading and Understanding Code

1. *B* inherits from *A: name, price* (*foo2* and *foo3* are overridden)
   C inherits from *B*: *name, price, foo2*, and *foo3* (*foo1* is overridden)
   
   ```
   A( ) called
   B( ) called
   ```
2. 
   ```
   B version of foo1( ) called
   ```
3. 
   ```
   A( ) called
   B( ) called
   C( ) called
   ```

10.10.3 Fill In the Code

```
private char middle;
public G( String f, String n, char middle )
{
  super( f, n );
  this.middle = middle;
```

1. `}`
2. `public class K extends F implements I`

10.10.4 Identifying Errors in Code

1. There is no error. `new D( )` returns a *D* object reference. *D* inherits from *C*; therefore a *D* object reference “is a” *C* object reference. Thus, it can be assigned to *c2*. Although a *C* object cannot be instantiated, a subclass object reference can be assigned to a superclass reference.
2. The *foo* method does not have a method body; it must be declared *abstract*. The *K* class must be declared *abstract* as well.

10.10.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. The instance variable *n* of class *M* is private, and is not inherited by *P*. Therefore, *n* is not visible inside class *P*.

11.15 Exercises, Problems, and Projects

11.15.1 Multiple Choice Exercises

1. *try/catch* blocks enable programmers to attempt to recover from illegal situations and continue running the program.
2. false
3. the contents of the file, if any, will be deleted.

4. the *stream* method

11.15.2 Reading and Understanding Code

1. ABCD
2. count = 3
3. Nice finish
4. CS1
   0
   1
   2
   3
   4

11.15.3 Fill In the Code

1. 
```
while ( parse.hasNext( ) )
{
  s = parse.next( );
  if ( s.equals( "C" ) )
    break;
}
```

2. 
```
while ( file.hasNext( ) )
{
  result += file.nextLine( ) + " ";
}
file.close( );
System.out.println( result );
```

```
average += grades[i];
. . .
average /= grades.length;
. . .
pw.println( average );
```

3. `pw.close( );`

11.15.4 Identifying Errors in Code

1. The *next* method returns a *String*; the return value cannot be assigned to an *int* variable. Use *nextInt* instead.

11.15.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. The *catch* block is missing; you need to add it after the *try* block as follows:

```
catch ( IOException ioe )
{
  ioe.printStackTrace( );
}
```

2. When we try to read 3.5 as an *int*, the method generates an *InputMismatchException* and we execute the *catch* block. To fix the problem, replace 3.5 with 3, for example, or use the *nextDouble* method and change *number* to a *double*.

12.12 Exercises, Problems, and Projects

12.12.1 Multiple Choice Exercises

1. may or may not be *static*.
2. calls itself.
3. a run-time error.

12.12.2 Reading and Understanding Code

1. 0
2. 3
3. There is no output
4. *foo3* outputs the parameter *String* in reverse
5. 64

12.12.3 Fill In the Code

1. `return foo( s.substring( 2, s.length( ) ) );`

```
if ( n >= 1000 )     // base case
  return n;
else                 // general case
```

2. `  return foo( n * n );`

12.12.4 Identifying Errors in Code

1. In the *else* clause, the *return* keyword is missing.

12.12.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. The base case is not coded properly; it needs to return a value, not make another recursive call. Instead of *return foo(0)*, you can code *return* 1.
2. In the general case, the method makes the recursive call with the original *String* less the last two characters as the argument. Therefore, there should be two base cases:

when the *String* has 0 characters (that is, an empty *String*) and when the *String* has one character. Assuming this method counts the number of characters in the *String* argument, we can add the following code after the first base case:

```
else if ( s.length( ) == 1 )
     return 1;
```

13.14 Exercises, Problems, and Projects

13.14.1 Multiple Choice Exercises

1. Linked lists are easily expanded.
2. (7, *Ajay*, *NFL*)
3. (7, *Ajay*, *NFL*) and (5, *Joe, Sonic*)
4. *front* = 3, stores 54; *back* = 0, stores 62
5. *front* = 7; *back* = 6; the list is empty

13.14.2 Reading and Understanding Code

1. If the list is not empty, it resets it to empty and returns *true*. Otherwise, it returns *false*.
2. It outputs all the *Player* objects in the list whose *game* field is *Diablo*.

13.14.3 Fill In the Code

1.

```
previous.getNext( ).setNext(
                    previous.getNext( ).getNext( ).getNext( ) );
```

```
public LLNode( char newGrade )
{
   grade = newGrade;
   next = null;
```

2.

```
}
```

```
public LLNode setGrade( char grade )
{
  this.grade = grade;
  return this;
}
public LLNode setNext( LLNode next )
{
  this.next = next;
  return this;
```

3. `}`

```
public int numberOfItems( )
{
  int count = 0;
  LLNode current = head;
  while ( current != null )
  {
    count++;
    current = current.getNext( );
  }
  return count;
```

4. `}`

13.14.4 Identifying Errors in Code

1. The *getID* method belongs to the *Player* class and cannot be called using *head*, a *PlayerNode* object reference. The code should be
   `return head.getPlayer( ).getID( );`
2. The number of items in the queue would never increase and we would always be able to insert into that queue, eventually overwriting items that are in the queue. This is a logic error. Furthermore, the queue would always be considered empty since the number of items always has

the value 0. We would never be able to delete an item from the queue.

13.14.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. There is no *getHead* method in the *PlayerLinkedList* class. In order to get a copy of the *Player* object stored at the first node of the list, we can code a method returning the *Player*.

14.8 Exercises, Problems, and Projects

14.8.1 Multiple Choice Exercises

1. $O(n^2)$
2. $O(n)$
3. $n * (n + 1) / 2$
4. $O(n^2)$

14.8.2 Compute the Running Time of a Method

1. $O(n)$
2. $O(\log n)$

15.10 Exercises, Problems, and Projects

15.10.1 Multiple Choice Exercises

1. root
2. True
3. 0, 1, or 2 children

4. *O*(log *n*)

15.10.3 Fill In the Code

1. `nd.getRight( ).setRight( null );`

```
public boolean hasExactlyOne( )
{
  // Your code goes here
  return ( root != null && root.getLeft( ) == null
                        && root.getRight( ) == null );
```

2. `}`

```
public int numberOfOddValues( )
{
  // Your code goes here
  return numberOfOddValues( root );
}
private int numberOfOddValues( IntegerNode nd )
{
  // Your code goes here
  if( nd == null )
       return 0;
  else if( nd.getData( ) % 2 == 1 ) // odd
        return 1 + numberOfOddValues( nd.getLeft( ) )
               + numberOfOddValues( nd.getRight( ) );
  else // not odd
        return numberOfOddValues( nd.getLeft( ) )
               + numberOfOddValues( nd.getRight( ) );
```

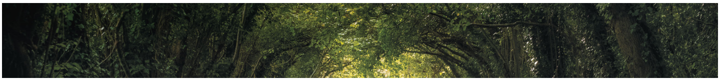
3. `}`

15.10.4 Identifying Errors in Code

1. When the value we are trying to delete is not found, the *private delete* method will eventually return the root of the binary search tree. Unless the tree is empty, the root is not *null* and the *public delete* method will return *true*. Furthermore, the *public delete* method will not properly work either.

15.10.5 Debugging Area—Using Messages from the Java Compiler and Java JVM

1. We need to test if *nd* is not *null* before calling *getData*, …



Index

Note: Page numbers followed by *f* or *t* indicate material in figures or tables respectively; **bold** page numbers are in Chapters 16, Chapter 17, or Appendix E, which are available in the eBook.

    getTitle method, **926**
    invertDelta method, **925**
    MixColors class, **929**
    RGBColorMixer class, **923–925**
    RGBColorMixerController class, **927–928**
    UML diagram, **923*f***
  example of (programming activity), **940–943**
  flow layout, **909**
  grid layout
    actionPerformed method, **912**
    ChessBoard class, **910–912**

        - constructors, **910*t***
        - GridButton class, **916–917**
        - PlayTilePuzzle class, **920–921**
        - possibleToPlay method, **916**
        - setUpGame method, **916**
        - TilePuzzle class, **912–915, 918*f***
        - TilePuzzleViewController Class, **918–920, 918*f***
        - won method, **916**
- L1 cache, 4, 5*t*
- L2 cache, 4–5, 5*t*
- length method (String class), 81*t*, 82–83, 88
- length of arrays, 349, 361, 431–432
- less than operator (<), 163, 163*t*, 165*t*, 194*t*
- less than or equal to operator (<=), 163, 163*t*, 165*t*, 194*t*
- LIFO. *See* last in, first out
- line feed character, 104*t*
- lines method, 598
- lineTo method (GraphicsContext class), 151*t*, 152
- linked lists, 696–726, 696*f*
    - defined, 696
    - doubly linked lists, 749–753
    - generic types, 753–758
    - implemented queues with, 722–726
    - implementing stacks with, 720–722
    - methods of, 699–705, 713–716
    - nodes, 696–697
    - of objects, 707–719
    - recursively defined, 758*f*, 759–765
    - sorted, 739–746
        - example of (programming activity), 746–749
    - testing, 705–707, 716–719
- LinkedListTest class, 757–758
- listener, **972**
- literal values, 41
- load method (FXMLLoader class), **965*t***
- local area network (LAN), 6
- local scope, 285–286
- logical operators, 164–167, 164*t*
    - DeMorgan’s Laws, 167–168, 167*t*, 235
    - loop conditions, constructing, 235
    - truth table for, 164, 164*t*
    - working of, 165–166
- logic errors, 24, 24*t*, 48, 216, 566
    - No-op effect, 292

login procedure, 86
log method (Maths class), 110*t*
long data type, 39, 39*t*, 42*t*, 58*t*
LongStream interface, 596
loop body, 215
loop continuation condition, 234, 235
loop control variables, 246, 248–249, 249*f*, 252, 259
  decrementing, 252
  incrementing, 248–249
  scope of, 247
looping, 19, 162, 213–264, 214
  array operations
    multidimensional arrays, 436–448
    single-dimensional arrays, 354–358, 360–362
  conditions for
    compound, 236–237, 237*f*
    constructing, 234–237
    incorrect, 235
    loop continuation condition, 234, 235
    loop termination condition, 234, 235
    steps in, 235
  count-controlled loops using for loop, 244–247
  do/while loop, 239–241
  endless loop, 216
  event-controlled, 214–215, 217–222
    text file, reading data from, 219–222
    user, reading data from, 217–219
    using do/while loop, 239–241
    using while loop, 214–215, 217–219
  for loops, 392, 407
    basic structure of, 244–245
    constructing, 246–256
    count-controlled loops using, 244–257
    example of (programming activity), 262–264
    flow of control, 245, 245*f*
    nesting, 257–261
    single-dimensional array operations, 354–358, 360–362
    syntax, 244
    testing techniques for, 256–257
    two-dimensional array operations, 436–448
  infinite loop, 216
  iteration, 215
  loop update statement, 216
  nested loops, 257–261

  - recursion *vs.*, 682
  - scanner, type-safe input using, 232–234, 234*f*
  - techniques for, 222–231
    - accumulation, 222–224
    - average, 227–229, 228*f*
    - counting, 224–227, 403–405
    - finding maximum/minimum values, 229–231
  - through ArrayList objects, 461–463
  - while loops, 257, 394
    - example of (programming activity), 241–244
    - nesting, 257–261
    - testing techniques for, 237–238
  - zero iterations, 215
- loop termination condition, 234, 235
- loop update statements, 216
  - for loops, 244–247, 249, 253

M

- machine language, 14
- Mac OS, system information, 7, 9*f*
- mapToDouble method, 600, 614
- Math class, 95, 106–107, 109–114
  - abs method, 107, 111, 180, 186
  - methods of, 110, 110*t*
  - min and max methods, 113–114, 113*f*
  - pow method, 111–112, 112*f*
  - round method, 112–113, 113*f*
  - static constants of, 107, 110*t*, 119
- maximum values, finding, 176–177, 229–231
  - among array elements, 357–358, 358*f*
- max method (Math class), 110*t*, 113–114, 113*f*
- members of classes, 77, 278. *See also* instance variables; methods; objects
  - inherited, 498–502
  - interface members, 537
  - protected (access modifier), 512–517
  - static, 307–309, 308*t*
- memory, 3–5, 4*t*, 5*t*
  - allocation, 347
- merge sort, 670–676
- meta-characters, 587
- methods, 15, 18, 35, 76
  - abstract, 521–529
  - arrays as parameters, 448–451

- of BigDecimal class, 187*t*
- calling, 18, 76, 79–84, 80*f*, 162
  - constructors, 502–505
  - example of (programming activity), 93–94
  - implicit vs. explicit invocation, 502
- of Character wrapper class, 119*t*
- of Double wrapper class, 118*t*
- for enum objects, 320, 320*t*
- of GraphicsContext Class, 141*t*
- inherited, 498–502
- of Integer wrapper class, 118*t*
- of Math class, 110*t*
- non-static, 308*t*, 309
- of NumberFormat class, 115*t*
- overloading, 284, 510, 511, 511*t* (*See also* inheritance)
  - overriding vs., 510, 511, 511*t*
- overriding, 303, 498, 508–511
  - overloading vs., 510, 511, 511*t*
- passing an argument to, 18
- of PrintStream class, 108*t*
- protected (access modifier), 500
- public *vs.* private, 81
- Scanner class, 219, 220*t*
- of Scanner class, 101*t*
- static, 308, 308*t*
- user-defined, 280–282
  - accessor methods, 286–289
  - constructors, 282–286
  - data manipulation methods, 293–296
  - exceptions, 617–619
  - mutator methods, 289–293
  - *this* reference, 299–303
  - toString and equals methods, 303–306

milesPerGallon method (Auto class API), 295, 352*t*, 468*t*

millis (Duration class), **1029*t***

minimum values, finding, 176–177, 177*f*, 229–231
- among array elements, 357–358

min method (Math class), 110*t*, 113–114, 113*f*

minus (–)
- decrement operator (– –), 59–60, 62*t*, 63*t*
- shortcut subtraction operator (– =), 61, 62, 63*t*
- subtraction operator (–), 50, 50*t*, 52*t*, 63*t*

minutes (Duration class), **1029*t***

MixColors class, **929**

mixed-type arithmetic, 57–59
MixingColorsController controller, **983**–**984**
mix method, **983**
Model-View-Controller architecture, **972**
modulus operator (%), 50, 52*t*, 54–56, 63*t*, 259
  shortcut modulus operator (%=), 61, 62, 63*t*
moneySpentOnGas method, 295
monthly temperatures, graphical representation of, 136–137, 136*f*
MouSeevent class, **896**, **896*t***, **902**, **1047**
mouse events, **1047**–**1061**
MouseListener interface, **896**, **896*t***
MouseMotionListener interface, **903**, **904*t***
mouse movements
  getInsets method, **901**, **902*t***
  Insets class, **901**, **902*t***
  model-view-controller architecture, **897**
  MouseAdapter class, **896**
  mouseClicked method, **901**
  MouSeevent class, **896**, **896*t***, **902**
  MouseListener interface, **896**, **896*t***
  MouseMotionListener interface, **903**, **904*t***
  mouseMoved method, **908**
  PlaySubHunt class, **903**
  repaint method, **902**, **902*t***
  setTitle method, **902**
  SubHunt class, **897**–**899**
  SubHunt draw method, **902**
  SubHuntViewController class, **899**–**901**
  translate method, **902**, **903*t***
moveTo method (GraphicsContext class), 151*t*, 152
Movie Record class, 605
MovieWinners class, 378–380, 392
multidimensional arrays, 425–476
  accessing elements of, 431–435
  aggregate operations, 436–448
    displaying data as bar chart, 445–448
    printing array elements, 437–438
    processing all elements, 436–438
    processing columns sequentially, 443–445
    processing given column, 440–441
    processing given row, 438–439
    processing rows sequentially, 441–443
  assigning initial values, 429–431
  declaring and instantiating, 426–431

  example of (programming activity), 451–456
multiplication operator (*), 37, 50, 50*t*, 52*t*, 63*t*
  shortcut multiplication operator (*=), 61, 62, 63*t*
multiply method (Rational class), 312
mutator methods, 107, **980**
  public, 289
  writing, 289–293

N

name collisions, **967**
name precedence, 292
namespace, **967**
NaN. *See* Not a Number
n-dimensional array, structure of, 456, 456*t*
negative integer, D-1–D-2
nested *if/else* statements, 177–180
nested loops, 257–261
nesting
  loops, 257–261
  processing multidimensional arrays, 436–448
networks, 3
new keyword
  instantiating ArrayList objects, 459–460
  instantiating arrays, 347, 348
newRatings parameter, 407
nextBoolean method (Scanner class), 101*t*, 103, 220*t*
nextByte method (Scanner class), 101*t*, 103, 220*t*
nextDouble method (Scanner class), 101*t*, 103, 220*t*
nextFloat method (Scanner class), 101*t*, 103, 220*t*
nextInt method (Random class), 99–100, 99*t*
nextInt method (Scanner class), 101*t*, 103, 104, 220*t*, 222, 568, 574
nextLine method (Scanner class), 101*t*, 105, 233, 233*t*, 251, 574
nextLong method (Scanner class), 101*t*, 103, 220*t*
next method (Scanner class), 101*t*, 103, 220*t*
nextShort method (Scanner class), 101*t*, 103, 220*t*
Node class, **1048**, **1059**
  using generics, 754–755
non-static methods, 308*t*, 309
No-op effect, 292
NoSuchElementException exception, 573, 575, 579, 589
Not a Number (NaN), 56
not equal operator (!=), 194*t*
NOT operator (!), 164, 164*t*, 194*t*, 235
null object references, 84–85, 85*f*, 282, 299, 348

NullPointerException exception, 84–85, 283, 353, 353*f*, 435, 567, 567*f*, 592, 704, 722, 726, **966**
NumberAxis class, **1071**
Number class, **1069**
NumberFormat class, 95, 114–116, 115*t*, 116*f*, 357
NumberFormatException exception, 567*f*, 570, **975**

O

object, 34
Object class, 189, 303, 363, 461, 497–498, 500, 537, 757
ObjectInputStream class, 576*t*, 610
object-oriented programming (OOP), 15–16, 76
ObjectOutputStream class, 576*t*, 608–610, 608*t*
object references, 76, 78–79, 80*f*, 82, 84–85
  null object references, 84–85, 85*f* (*See also* null object references)
  this reference, 299–303
objects, 15
  array of, 347, 351–352
  arrays of, 426–431
    sorting, 391–392
  comparing
    equals method, 189–190, 190*f*
    Strings method, 190–192, 190*t*, 192*f*
  creating
    with constructors, 78–79
    with factory methods, 115
  enum, 319–320, 320*t*
  generic, 697

P

packages, 95, 95*t*
  user-defined, 327
palindrome search (example), 654–658
Pane class, **1018*t***
parallel arrays, 378, 380
ParallelTransition, **1024**, **1032–1033**, **1034*t***
parameterized types, 458, 753–758
Parent, **967**, **1035**
parentheses ( ), 52, 52*t*, 63*t*, 81, 82, 194*t*, 498
  array length, 349
  calling methods, 81

parse, 587–589
parseDouble method (Double class), 118*t*, **975**
parseInt method (Integer wrapper class), 118*t*
parsing a String using Scanner, 587–589
passing an argument to method, 18. *See* argument(s)
passing test scores, counting, 225–226, 226*f*
PasswordSecurityHandler class, 540
PasswordSecurityHandlerClient class, 542
Paths class, 598, 599*t*
paths, drawing, 151–153
percent sign (%)
  in DecimalFormat class pattern, 96*t*
  shortcut modulus operator (%=), 61, 62, 63*t*
performance
  of CPU, 4
  iteration *vs.* recursion, 682
  protected access modifier, 512
period (.), 353
  in DecimalFormat class pattern, 96*t*
  dot notation, 81–82
  with static class members, 309
  in System class, 108
Perl, 15
personal computer (PC), design of, 3
PHP, 15
PI constant (Math class), 109–110, 110*t*, 307
PieChart class, **1062**–**1063**, **1064*f***
pixel, 140–141
PixelReader interface, **996*t***
PixelWriter interface, **997*t***
play (AudioClip class), **1031*t***
PlayColorCount class, **938**–**939**, **1045**–**1046**
Player class, 697, 707–709
PlayerLinkedList class, 714–715, 714*t*
PlayerLinkedListTest class, 716–719
PlayerNode class, 709–710
  for doubly linked list, 750
PlayerQueueLinkedList class, 723*t*, 724–726
PlayerSortedLinkedList class, 741, 741*t*, 742–744
PlayerSortedLinkedListTest class, 745
PlayerStackLinkedList class, 720*t*, 721–722
play head, **1034**
play method, **1024**, **1053**, **1057**, **1059**
PlaySubHunt class, **1053**

PlayTilePuzzle class, **920–921**, **1019**
PlayTreasureHunt class, **1060–1061**
plus (+)
  addition operator (+), 50, 50*t*, 52*t*, 63*t*
  concatenation operator for Strings (+), 86–88
  increment operator (++), 59–60, 62*t*, 63*t*
  shortcut addition operator (+=), 61, 62, 62*t*, 63*t*, 87
polymorphism, 529–531
  example of (programming activity), 531–536
popping items from stacks, 720–722, 726–730
possibleToPlay method, **916**, **1014**
postfix operators, 60–61
pound sign. *See* hash (#)
power of 2, 11–12, 11*t*
pow method (Math class), 110*t*, 111–112, 112*f*
precedence
  name, 292
  operator, 51–53, 52*t*, 63*t*

pushing items into stacks, 720–722, 726–730
Python, 15

Q

question mark for conditional operator (?:), 192–194
queues
  array representation of, 733–739
  defined, 722, 722*f*
  implemented with linked lists, 722–726
quick sort, 676–681

R

radio buttons, **977–985**
  JavaFX class, **968*t***
radio buttons vs.checkboxes, **884*t***
Random class, 95, 99–100
random numbers, generation of, 99–100
Rational class, 309–315
rational number, representation of, 309
reading data into arrays, 355–356, 356*f*

readObject method (ObjectInputStreamclass), 610–614
record class, 590
recursion, 638–682
  array, 659–660
  binary search, 661–664
  identifying base and general cases, 638–640
  iteration *vs.*, **990**–**991**
  linked lists defined by, 758*f*, 759–765
  merge sort, 670–676
  palindrome search (example), 654–658
  quick sort, 676–681
  with return values, 641–647
    calculating factorials, 641–647
    calculating greatest common divisor, 647–652
  Towers of Hanoi (example), 665–670
  two base cases, 652–654
recursiveBinarySearch method, 662
RecursiveLinkedList class, 759*t*, 760–761
RecursiveLinkedListTest class, 763–764
recursive method, 638
recursivePalindrome method, 656
recursiveTOfH method, 667, 669
referenced, 172
  access modifiers, 279
Region, **967**
register, **974**
regular expression, 587
relational operators, 163, 163*t*
remote server, reading formatted open data from
  accessing remote data, 601–602
  JSON formatting and parsing, 602–605
  reading, parsing, streaming, and processing remote data, 605–607
removeListener (ObservableValue interface), **1000*t***
remove method (ArrayList class), 461*t*
repetition, 214
reserved words, 35
resources, 573
return statement, 281
  in recursion methods, 641
return values (methods), 18, 80
  arrays as, 374, 448–451
  for constructors (error), 285
  recursion with, 641–647
reusability of code, 77

  generic classes, 458
  through interfaces, 537
RGB color, 141, 142*t*
RGBColorMixer class, **923–925**
RGBColorMixerController class, **927–928**
rollCount array, 403, 405
RotateTransition, **1024**, **1030–1031**, **1032*t***
rounding errors, 184
round method (Math class), 110*t*, 112–113, 113*f*
routers, 6
row index (multidimensional arrays), 431
rows of multidimensional arrays
  processing rows sequentially, 441–443
  processing single row, 438–439
rules of scope, 286, 286*t*
running time analysis, 783–807, 785*t*
  counting statements, 787–790
  evaluating recursive methods, 791–795
  of searching and sorting algorithms, 797–801
  sorting algorithms, 802–807
run-time errors, 23–24, 24*t*
runTransition method, **1029**

S

ScaleTransition, **1024**, **1032**, **1033*t***, **1082**
Scanner class, 95, 251, 568, 571, 571–572*t*, 576*t*, 587*t*, 602*t*
  for character input, 103–104
  constructor, 101*t*
  hasNext method, 574
  methods for testing tokens, 233*t*
  parsing a String, 587–589
  reading data from text files, 219–222, 587–592
  reading user input from the Java console, 100–106
  type-safe input using, 232–234, 234*f*
Scene class, **965**, **965*t***, **1076**, **1083**
scene graph, **962**
scope, 172
  block scope, 172
  class scope, 280
  local scope, 285–286
  loop control variable, 247
  rules of, 286, 286*t*
searching arrays
  Binary Search algorithm, 392–396

  example of (programming activity), 396–401
  recursive binary search, 661–664, 797–801
  sequential search, 378–381, 392
seconds (Duration class), **1029*t***
securityLevel method, 542
Seed value, 99
select (SingleSelectionModel class), **991*t***
selection (program flow control), 18, 19, 162
  conditional operator (?:), 192–194
    vs. if/else, 193
  dangling else clauses, 178–180
  if/else if statements, 173–175, 174*f*
  if/else statements, 170–172, 170*f*
    example of (programming activity), 182–184
    nested, 177–180
    sequential, 176–177
  if statement, 168–170, 168*f*
  testing techniques, 180–182
Selection Sort (arrays), 381–385, 385*f*, 797
selectionSort method, 384
Seller class, 406–407
SellerRatings class, 407–408, 408*f*
semicolon (;)
  abstract method definition, 537
  in abstract methods, 521
  after conditions (error), 169, 170, 245
  after the condition, 216
  for loop, 244
sentence backward, printing, 252–253, 253*f*
sentinel value, 215, 217–219, 218*f*, 222–224, 226, 228–229, 234, 238
sequential execution, 162
sequential *if/else* statements, 176–177
sequential processing, 17
sequential search, 379
  of sorted arrays, 392
  of unsorted array, 378–381
Sequential Search algorithm, 790
sequentialSearch method, 400

The blocks in the diagram are labeled motherboard, input, Output, and Secondary storage. The motherboard contains a C P U with L 1 cache, L 2 cache, and main memory. The C P U with L 1 cache and the L 2 cache have bidirectional data transfer. The L 2 cache and Main memory also have bidirectional data transfer. The input devices are keyboard and L A N. The input devices transmit data to the Motherboard. The output devices are monitor, printer and L A N. The motherboard transfers data to the Output devices. The hard disk is the secondary storage device. The motherboard and the Secondary storage device have bidirectional data transfer between them.

The data in the bar chart is as follows. J a n: 31. F e b: 24. M a r: 45. A p r: 60. May: 69. J u n: 80. J u l: 88. A u g: 87. S e p: 75. O c t: 65. N o v: 43. D e c: 23. The bars for J a n, Feb, Mar, Nov, and Dec are colored blue. The bars for Apr, May, Sep, and Oct are colored yellow. The bars for Jun, Jul, and Aug are colored red.

Back to Figure

The x axis increases from left to right and the y axis increases from top to bottom. The origin, (0, 0), is at the top left corner. The coordinates at the top right, bottom left and bottom right corners are as follows: (699, 0), (0, 399), and (699, 399). The coordinates marked in the coordinate system are as follows: (75, 60), (150, 250), (350, 250), (550, 300), and (625, 95).

Back to Figure

The first diagram shows a horizontal line. The coordinates of the left end of the line are x Start and y Start. The coordinates of the right end of the line are x End and y End. The method for drawing the line is as follows: stroke Line, left parentheses, x Start, comma, y Start, comma, x End, comma, y End, right parentheses. The second diagram shows a filled rectangle. The horizontal and vertical dimensions of the filled rectangle are labelled Width and Height, respectively. The coordinates of the top left corner of the rectangle are x and y. The method for drawing the filled rectangle is as follows: fill Rect, left parentheses, x, comma, y, comma, width, comma, height, right parentheses. The third diagram shows a filled oval within a dashed rectangle. The edges of the rectangle are tangential to the topmost, bottommost, leftmost, and rightmost points of the oval. The horizontal and vertical dimensions of the dashed rectangle are marked Width and Height, respectively. The method for drawing the filled oval is as follows: fill Oval, left parentheses, x, comma, y, comma, width, comma, height, right parentheses. The fourth diagram shows a caption which is as follows: a string is written here. The coordinates of the leftmost character of the string are x and y. The method for the string is as follows: fill Text, left parentheses, string, comma, x, comma, y, right parentheses.

Back to Figure

The window has 3 lines. A thick green diagonal line runs from the top left to the bottom right. A thick red horizontal line is to the top right of the diagonal line. A thin vertical black line is to the bottom left of the diagonal line.

Back to Figure

The window has 4 shapes. The shape on the left is a blue filled oval within a rectangle. The shape at the center is a filled blue square. The shape at the bottom right is a filled green circle. The shape on the bottom left is an oval.

Back to Figure

The window displays 2 identical strings. The text within the string reads: Programming is not a spectator sport, exclamation mark. The first string has a smaller font size relative to the second string.

Back to Figure

The shapes in the image from top to bottom are as follows: a filled brown rectangle, a horizontal filled line, a vertical red filled oval, a small dark red oval within the larger oval, and 2 filled brown ovals at the bottom of the large oval.

Back to Figure

The table has 2 columns labeled Return Value and Method name and argument list. The row entries are as follows. Row 1. Return Value: void. Method name and argument list: begin Path, left parentheses, right parentheses, sets the drawing path to empty. Row 2. Return Value: void. Method name and argument list: move To, left parentheses, double x, comma, double y, right parentheses, moves to the left parentheses, x, comma, y, right parentheses, location without adding a line to the path. Row 3. Return Value: void. Method name and argument list: line To, left parentheses, double x, comma, double y, right parentheses, adds a line to the current path fro the previous location to left parentheses, x, comma, y, right parentheses. Row 4. Return Value: void. Method name and argument list: close Path, left parentheses, right parentheses, closes the path by adding a line from teh previous location to the first location of the path. Row 5. Return Value: void. Method name and argument list: stroke, left parentheses, right parentheses, draws the path using the current stroke color. Row 6. Return Value: void. Method name and argument list: fill, left parentheses, right parentheses, draws teh path using the current fill color.

Back to Figure

“Line 1: 75, right angled bracket, 18, 2 ampersand signs, 75, left angled bracket, 65 is false. Line 2: 75, left angled bracket, 65, 2 ampersand signs, 75, right angled bracket, 18 is false. Line 3: 75, right angled bracket, 65, 2 pipes, 75, left angled bracket, 18 is true. Line 4: 75, right angled bracket, 65, 2 pipes, 75, left angled bracket, 18, 2 ampersand signs, false is true. Line 5: left parentheses, 75, right angled bracket, 65, 2 pipes, 75, left angled bracket, 18, right parentheses, 2 ampersand signs, false is false. ”

Back to Figure

The steps in the flowchart are as follows. Step 1: condition, question mark. If Step 1 is true, go to step 2, else go to step 3. Step 2: true block. Step 3: next statement.

Back to Figure

“Line 1: Enter your test grade, right angled bracket, 85. Line 2: Enter your extra credit, right angled bracket, 10.

Line 3: Your final test grade is 95. ”

Back to Figure

Line 5: balance is dollar sign, 5.00, semicolon, monthly fee is dollar sign, 7.50. Line 6: blank. Line 7: Applying the monthly fee, colon. Line 8: Warning, colon, account is overdrawn, exclamation mark. Line 9: balance is negative, dollar sign, 2.50, semicolon, monthly fee is dollar sign, 7.50.

Back to Figure

The classes shown in the diagram are as follows: Object, Bank Account, Checking Account, and Savings Account. The method under the Object class is as follows: to String, left parentheses, right parentheses, colon, String. The attributes under the Bank Account class are as follows: MONEY, colon, Decimal Format, equals, dollar sign, hash, comma, hash, hash, 0.00, balance, colon, double. The methods under the Bank Account class are as follows: Bank Account, left parentheses, right parentheses, Bank Account, left parentheses, double, right parentheses, get Balance, left parentheses, right parentheses, colon, double, deposit, left parentheses, double, right parentheses, colon, Bank Account, withdraw, left parentheses, double, right parentheses, colon, Bank Account, to String, left parentheses, right parentheses, colon, String. The Bank Account class inherits from the Object class and it is represented by an arrow from the Bank Account class to the Object class. The attributes under the Checking Account class are as follows: DEFAULT underscore FEE, colon, double, equals, 5.00, monthly Fee, colon, double. The methods under the Checking Account class are as follows: Checking Account, left parentheses, right parentheses, Checking Account, left parentheses, double, comma, double, right parentheses, apply Monthly Fee, left parentheses, right parentheses, colon, Checking Account, get Monthly Fee, left parentheses, right parentheses, colon, double, set Monthly Fee, left parentheses, double, right parentheses, colon, Checking Account, to String, left parentheses, right parentheses, colon, String. The Checking Account class inherits from the Bank Account class and it is represented by an arrow from the Checking Account Class to the Bank Account class. The attributes of the Savings Account class are as follows: DEFAULT underscore RATE, colon, double, equals, 0.03, interest Rate, colon, double. The methods under the Savings Account are as follows: Savings Account, left parentheses, right parentheses, Savings Account, left parentheses, double, comma, double, right parentheses, apply Interest, left parentheses, right parentheses, colon, Savings Account, get Interest Rate, left parentheses, right parentheses, colon, double, set Interest Rate, left parentheses, double, right parentheses, colon, Savings Account, to String, left parentheses, right parentheses, colon, String. The Savings Account class inherits from the Bank Account class and it is represented by an arrow from the Savings Account class to the Bank Account class.

Back to Figure

The window has 6 buttons which are as follows: Change interest rate, Apply interest, Deposit, Withdraw, Display account information, Exit. The table below the buttons has 3 columns labeled, Activity, Balance, and Interest Rate. The row entry is as follows: Activity: Account opened. Balance: 300.00 dollars. Interest Rate: 4.00 percent.

Back to Figure

The window has 6 buttons which are as follows: Change interest rate, Apply interest, Deposit, Withdraw, Display account information, Exit. The table below the buttons has 3 columns labeled, Activity, Balance, and Interest Rate. The row entries are as follows. Row 1. Activity: Account opened. Balance: 300.00 dollars. Interest Rate: 4.00 percent. Row 2. Activity: Deposit. Balance: 550.00 dollars. Interest Rate: 4.00 percent. Row 3. Activity: Interest applied. Balance: 551.83 dollars. Interest Rate: 4.00 percent. Row 4. Activity: Withdrawl. Balance: 451.83 dollars. Interest Rate: 4.00 percent. Row 5. Activity: Rate changed. Balance: 451.83 dollars. Interest Rate: 5.00

percent. Row 6. Activity: Interest applied. Balance: 453.72 dollars. Interest Rate: 5.00 percent.

Back to Figure

The diagram has the following classes: Object, Figure, Circle, and Square. The object class does not have attributes or methods. The Figure class inherits from the Object class and it is represented by an arrow from the Figure class to the Object class. The attributes of the Figure class are as follows: x, colon, int, y, colon, int, color, colon, color. The methods of the Figure class are as follows: Figure, left parentheses, right parentheses, Figure, left parentheses, int, comma, int, comma, Color, right parentheses, get Color, left parentheses, right parentheses, colon, Color, set Color, left parentheses, Color, right parentheses, colon, Figure, get X, left parentheses, right parentheses, colon, int, set X, left parentheses, int, right parentheses, colon, Figure, get Y, left parentheses, right parentheses, colon, int, set Y, left parentheses, int, right parentheses, colon, Figure, draw, left parentheses, Graphics Context, right parentheses, colon, void. The Circle and the Square classes inherit from the Figure class and this is represented by arrows from the Circle and the Square classes to the Figure class. The attributes of the Circle class are as follows: MIN underscore RADIUS, colon, int, radius, colon, int. The methods under the Circle class are as follows: Circle, left parentheses, right parentheses, Circle, left parentheses, int, comma, int, comma, Color, comma, int, right parentheses, get Radius, left parentheses, right parentheses, colon, int, set Radius, left parentheses, int, right parentheses, colon, Circle, draw, left parentheses, Graphics Context, right parentheses, colon, void. The attributes under the Square class are as follows: MIN underscore LENGTH, colon, int, length, colon, int. The methods under the Square class are as follows: Square, left parentheses, right parentheses, Square, left parentheses, int, comma, int, comma, Color, comma, int, right parentheses, get Length, left parentheses, right parentheses, colon, int, set Length, left parentheses, int, right parentheses, colon, Square, draw, left parentheses, Graphics Context, right parentheses, colon, void.

Back to Figure

The window has a text label, a text box, and 2 buttons. The text label reads: Enter t, left parentheses, Tortoise, right parentheses, or h, left parentheses, Hare, right parentheses. The entry in the text box reads: h. The labels of the 2 deactivated buttons are Enter Racer and Start. The image below displays a hare near a tortoise.

Back to Figure

The classes in the U M L diagram are as follows: Object, Racer, Tortoise, and Hare. The Object class does not have attributes or methods. The attributes of the Racer class are as follows: I D, colon, String, x, colon, int, y, colon, int. The methods under the Racer class are as

follows: Racer, left parentheses, right parentheses, Racer, left parentheses, String, comma, int, comma, int, right parentheses, get I D, left parentheses, right parentheses, colon, String, get X, left parentheses, right parentheses, colon, int, set X, left parentheses, int, right parentheses, colon, Racer, get Y, left parentheses, right parentheses, colon, int, set Y, left parentheses, int, right parentheses, colon, Racer, move, left parentheses, right parentheses, colon, void, draw, left parentheses, Graphics Context, right parentheses, colon, void. The Racer class inherits from the Object class and it is represented by an arrow from the Racer to the Object class. The Tortoise and Hare classes inherit from the Racer Class. The attributes under the Tortoise class are as follows: rand, colon, Random, speed, colon, int. The methods under the Tortoise class are as follows: Tortoise, left parentheses, right parentheses, Tortoise, left parentheses, String, comma, int, comma, int, right parentheses, move, left parentheses, right parentheses, colon, void, draw, left parentheses, Graphics Context, right parentheses, colon, void. The Hare class does not have attributes. The methods under the Hare class are as follows: Hare, left parentheses, right parentheses, Hare, left parentheses, String, comma, int, comma, int, right parentheses, move, left parentheses, right parentheses, colon, void, draw, left parentheses, Graphics Context, right parentheses, colon, void.

Back to Figure

The window has a text label, a text box, and 2 buttons.

The text label reads: Enter t, left parentheses, Tortoise, right parentheses, or t, left parentheses, Hare, right parentheses. The entry in the text box reads: h. The labels of the 2 deactivated buttons are Enter Racer and Start. The image below displays 3 hares and 4 tortoises.

Back to Figure

The interfaces are labeled String Handler and Validator. The classes are labeled Password Security Handler and Hex String Handler. The 4 methods under the String Handler interface are as follows. process Digit, left parentheses, char, right parentheses, colon, void. process Letter, left parentheses, char, right parentheses, colon, void. process Other, left parentheses, char, right parentheses, colon, void. parse, left parentheses, String, right parentheses, colon, void. The method under the Validator interface is as follows. is Valid, left parentheses, right parentheses, colon, boolean. The attributes under the Password Security Handler class are as follows. length, colon, int. digit, colon, boolean. other Character, colon, boolean. The methods under the Password Security Handler class are as follows. Password Security Handler, left parentheses, right parentheses. process Digit, left parentheses, char, right parentheses, colon, void. process Letter, left parentheses, char, right parentheses, colon, void. process Other, left parentheses, char, right parentheses, colon, void. security Level, left parentheses, right parentheses, colon, String. The attributes under the Hex String Handler class are as follows. valid Hex, colon, boolean, number, colon, int. The methods under the Hex String Handler class are as follows. Hex String Handler, left parentheses, right parentheses. process Digit, left parentheses, char, right parentheses, colon, void. process Letter, left parentheses, char, right parentheses, colon, void. process Other, left parentheses, char, right parentheses, colon, void. is Valid, left parentheses, right parentheses, colon, boolean. get Number, left parentheses, right parentheses, colon, int. 2 dashed arrows are drawn from the Password Security Handler class and the Hex String Handler class to the String Handler interface. A dashed arrow is drawn from the Hex String Handler class to the Validator interface.

Back to Figure

Line 1: A strong password has at least 8. Line 2: characters and contains at least one digit. Line 3. and one special character. Line 4. Enter a password, right angled bracket, open, at symbol, j b c. Line 5. open, at symbol, j b c, single quote, s, security is medium.

Back to Figure

Line 1: Enter a hexadecimal number, right angled bracket, A 5 6 E. Line 2: A 5 6 E equals 42350.

Back to Figure

The interface is labeled Shipping Cost. The 3 classes are labeled Flat Rate Shipping, Standard Shipping and

Express Shipping. The method under the Shipping Cost interface is as follows. calculate Shipping, left parentheses, double, right parentheses, colon, double. The attribute under the Flat Rate Shipping class is RATE underscore PER underscore POUND, colon, double. The method under the Flat Rate Shipping class is calculate Shipping, left parentheses, double, right parentheses, colon, double. The attributes under the Standard Shipping class are as follows. BASE underscore WEIGHT, colon, double, BASE underscore CHARGE, colon, double, EXTRA underscore POUND underscore RATE, colon, double. The method under the Standard Shipping class is calculate Shipping, left parentheses, double, right parentheses, colon, double. 2 dashed arrows are drawn from the Flat Rate Shipping and the Standard Shipping classes to the Shipping Cost interface. The attribute under the Express Shipping class is EXPRESS underscore SURCHARGE, colon, double. The method under the Express Shipping class is calculate Shipping, left parentheses, double, right parentheses, colon, double.

Back to Figure

Line 1: What is the weight of the item, question mark, 6.5. Line 2: Our shipping options are, colon. Line 3, indented once: 1 Express shipping, colon, 1 hyphen 2 business days. Line 4, indented once: 2 Standard shipping, colon, 3 hyphen 5 business days. Line 5, indented once: 3 Flat Rate, colon, 6 hyphen 8 business days. Line 6: Select your shipping option, right angled bracket, 1. Line 7: your shipping cost is dollar sign, 14.00.

Back to Figure

The classes in the U M L diagram are as follows: Object, Throwable, Exception, Runtime Exception, I O Exception, Illegal State Exception, No Such Element Exception, Arithmetic Exception, Illegal Argument Exception, Index Out Of Bounds Exception, Null Pointer Exception, File Not Found Exception, Input Mismatch Exception, Number Format Exception, String Index Out Of Bounds Exception, Array Index Out Of Bounds Exception. The Throwable class inherits from the Object class. The Exception class inherits from the Throwable class. The Runtime Exception and I O Exception classes inherit from the Exception class. The File Not Found Exception class inherits from the I O Exception class. The Illegal State Exception, No Such Element Exception, Arithmetic Exception, Illegal Argument Exception, Index Out Of Bounds Exception and Null Pointer Exception classes inherit from the Runtime Exception class. The Input Mismatch Exception class inherits from the No Such Element Exception class. The Number Format Exception class inherits from the Illegal Argument Exception class. The String Out Of Bounds Exception and Array Index Out Of Bounds Exception classes inherit from the Index Out Of Bounds Exception class.

Back to Equation

Line 1: f, left parentheses, n, right parentheses, less than or equal to, a subscript p, n superscript p, left parentheses, 1 plus M, left parentheses, negative 1, plus, left parentheses, n forward slash, left parentheses, n minus 1, right parentheses, right parentheses, right parentheses, right parentheses. Line 2: f, left parentheses, n, right parentheses, less than or equal to, a subscript p, n superscript p, left parentheses, 1 plus M, left parentheses, left parentheses, negative n plus 1 plus n, right parentheses, forward slash, left parentheses, n minus 1, right parentheses, right parentheses, right parentheses. Line 3: f, left parentheses, n, right parentheses, less than or equal to, a subscript p, n superscript p, left parentheses, 1 plus M, left parentheses, 1 forward slash, left parentheses, n minus 1, right parentheses, right parentheses, right parentheses.

Back to Equation

f, left parentheses, n, right parentheses, less than or equal to, a subscript p, n superscript p, left parentheses, 1 plus M, right parentheses, for n greater than or equal to 2.

Back to Equation

f, left parentheses, n, right parentheses, less than or equal to, c subscript 0, n superscript p.

Back to Equation

The table has 2 columns labeled Statement and hash

Times Executed. The row entries are as follows. Row 1. Statement: left parentheses, 1, right parentheses. Hash Times Executed: 1. Row 2. Statement: left parentheses, 2, right parentheses. Hash Times Executed: 1. Row 3. Statement: left parentheses, 3, right parentheses. Hash Times Executed: n plus 1. Row 4. Statement: left parentheses, 4, right parentheses. Hash Times Executed: n. Row 5. Statement: left parentheses, 5, right parentheses. Hash Times Executed: n. Row 6. Statement: left parentheses, 6, right parentheses. Hash Times Executed: 1.

Back to Table

Line 1: T, left parentheses, n, right parentheses, equals, 1 plus 1 plus, left parentheses, n plus 1, right parentheses, plus, n plus n plus 1. Line 2: Equals sign, 3 n plus 4. Line 3: Equals sign, O, left parentheses, n, right parentheses.

Back to Equation

The table has 2 columns labeled Statement and number of times executed. The row entries are as follows. Row 1. Statement: left parentheses, 1, right parentheses. Number of Times Executed: 1. Row 2. Statement: left parentheses, 2, right parentheses. Number of Times Executed: 1 plus, left parentheses, n plus 1, right parentheses, plus, n, equals, 2 asterisk n, plus, 2. Row 3. Statement: left parentheses, 3, right parentheses. Number of Times Executed: n asterisk, left parentheses, 1 plus, left parentheses, n plus 1, right parentheses, plus, n, right parentheses, equals, 2 asterisk n squared plus 2 asterisk n. Row 4. Statement: left parentheses, 4, right parentheses. Number of Times Executed: n asterisk n equals n squared. Row 5. Statement: left parentheses, 5, right parentheses. Number of Times Executed: between 0 and n asterisk n. Row 6. Statement: left parentheses, 6, right parentheses. Number of Times Executed: 1.

Back to Table

The equation is as follows. T, left parentheses, n, right parentheses, equals, 1 plus, left parentheses, 2 asterisk n plus 2, right parentheses, plus, left parentheses, 2 asterisk n squared plus 2 asterisk n, right parentheses, plus, left parentheses, n squared, right parentheses, plus, x plus, 1. This equals 3 asterisk n squared plus 4 asterisk n plus 4 plus x.

Back to Equation

The equations are as follows. Line 1: 3 asterisk n squared, plus, 4 asterisk n, 4, left angled bracket, equals sign, T, left parentheses, n, right parentheses, left angled bracket, equals sign, 3 asterisk n squared, plus, 4 asterisk n, plus, 4, plus, n squared. Line 2: 3 asterisk n squared, plus, 4 asterisk n, plus, 4, left angled bracket, equals sign, T, left parentheses, n, right parentheses, left angled bracket, equals sign, 4 asterisk n squared, plus, 4 asterisk n, plus 4.

Back to Equation

The table has 2 columns labeled Statement and number of times executed. The row entries are as follows. Row 1. Statement: left parentheses, 1, right parentheses. Number of times executed: 1 plus, left parentheses, between 1 and left parentheses, n plus 1, right parentheses, right parentheses plus left parentheses, between 0 and n, right parentheses. Row 2. Statement: left parentheses, 2, right parentheses. Number of times executed: between 1 and n. Row 3. Statement: left parentheses, 3, right parentheses. Number of times executed: 0 or 1. Row 4. Statement: left parentheses, 4, right parentheses. Number of times executed: 1 or 0.

Back to Table

The equations are as follows. Line 1: 1 plus, left parentheses, 1, right parentheses, plus, left parentheses, 0, right parentheses, plus, 1, plus, 1, left angled bracket, equals, T, left parentheses, n, right parentheses, left angled bracket, equals sign, 1 plus, left parentheses, n plus 1, right parentheses, plus, n plus n plus 1. Line 2: 4, left angled bracket, equals sign, T, left parentheses, n, right parentheses, left angled bracket, equals sign, 3 n plus 3.

Back to Equation

Line 1: T, left parentheses, n, right parentheses, equals, 1, plus, left parentheses, n plus 1, right parentheses, forward slash, 2, plus, n forward slash 2, plus, n forward slash 2, plus, 1. Line 2: Equals sign, 3 n, forward slash, 2, plus, 2 and a half. Line 3: equals sign, O, left parentheses, n, right parentheses.

Back to Equation

Line 1: T 1, left parentheses, n, right parentheses, equals, 1 plus T 1, left parentheses, n minus 1, right parentheses, plus 1. Line 2: equals sign, T 1, left parentheses, n minus 1, right parentheses, plus, 2. 2 forward slashes. Equation 14.1.

Back to Equation

T 1, left parentheses, x, right parentheses, equals, T 1, left parentheses, x minus 1, right parentheses, plus, 2, where x is some integer. 2 forward slashes. Equation 14.2.

Back to Equation

T 1, left parentheses, n minus 1, right parentheses, equals, T 1, left parentheses, n minus 2, right parentheses, plus, 2.

Back to Equation

T 1, left parentheses, n, right parentheses, equals, T 1, left parentheses, n minus 2, right parentheses, plus, 2, plus, 2. Line 2: Equals sign, T 1, left parentheses, n minus 2, right parentheses, plus, 2 asterisk 2. 2 forward slashes.

Equation 14.3.

Back to Equation

The equation reads: T 1, left parentheses, n minus 2, right parentheses, equals, T 1, left parentheses, n minus 3, right parentheses, plus, 2.

Back to Equation

The equation is as follows. Line 1: T 1, left parentheses, n, right parentheses, equals, T 1, left parentheses, n minus 3, right parentheses, 2, plus, 2 asterisk 2. Line 2: equals sign, T 1, left parentheses, n minus 3, right parentheses, plus, 2 asterisk 3. 2 forward slashes, Equaiton 14.4.

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo 1, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, n greater than 1, right parentheses. Line 4, indented twice: return, left parentheses, 2 asterisk foo 1, left parentheses, n forward slash 4, right parentheses, right parentheses, semicolon. Line 5, indented once: else. Line 6, indented twice: return 1, semicolon. Line 7: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, int, for. Line 1: public static void foo 2, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int i, equals, n, semicolon, i greater than 0, semicolon, i minus, minus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: for, left parentheses, int j equals 0, semicolon, j less than n, semicolon, j plus, plus, right parentheses. Line 6, indented twice: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 7, indented once: right brace. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, in, for. Line 1: public static void foo 3, left parentheses, int n, right parentheses. Line 2: Left brace. Line 3, indented once: for, left parentheses, int i equals 0, semicolon, i less than n, semicolon, i plus, plus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: for, left parentheses, int j equals 0, semicolon, j less than i, j plus, plus, right parentheses. Line 6, indented thrice: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 7, indented once: right brace. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, int, for. Line 1: public static void foo 4, left parentheses, int, left square bracket, right square bracket, left square bracket, right square bracket, a r r, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int i equals 0, semicolon, i less than a r r dot length, semicolon, i plus, plus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: for, left parentheses, int j equals a r r, left square bracket, i, right square bracket, dot, length minus 1, semicolon, j greater than or equal to 0, semicolon, j minus, minus, right parentheses. Line 6, indented thrice: System dot out dot print l n, left parentheses, double quotes, Hello world, double quotes, right parentheses, semicolon. Line 7, indented once: right brace. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, int, for. Line 1: public static void foo 5, left parentheses, int, left square bracket, right square bracket, left square bracket, right square bracket, left square bracket, right square bracket, a r r, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int i equals 0, semicolon, i less than a r r dot length, semicolon, i plus, plus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: for, left parentheses, int j equals 0, semicolon, j less than a r r, left square bracket, i, right square bracket, dot, length, semicolon, j plus, plus, right parentheses. Line 6, indented twice: left brace. Line 7, indented thrice: for, left parentheses, int k equals 0, semicolon, k less than a r r, left square bracket, i, right square bracket, left square bracket, j, right square bracket, dot length, semicolon, k plus, plus, right parentheses. Line 8, indented thrice: System dot out dot print l n, left parentheses, double quotes, Hello World, double quotes, right parentheses, semicolon. Line 9, indented twice: right brace. Line 10, indented once: right brace. Line 11: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, int, if, else. Line 1: public static void foo 6, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, n less than or equal to 0, right parentheses. Line 4, indented twice: System dot out dot print l n, left parentheses, double quotes, Hello world, double quotes, right parentheses, semicolon. Line 5, indented once: else. Line 6, indented twice: foo 6, left parentheses, n minus 1, right parentheses, semicolon. Line 7: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo 7, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, n, equals, equals, 0, right parentheses. Line 5, indented twice: return 0, semicolon. Line 6, indented once: else. Line 7, indented twice: return, left parentheses, n plus foo 7, left parentheses, n minus 1, right parentheses, right parentheses, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo 8, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 1. Line 4, indented once: if, left parentheses, n, equals, equals, 1, 2 pipes, n, equals, equals, 2, right parentheses. Line 5, indented twice: return 1, semicolon. Line 6, indented once: else. Line 7, indented twice: return, left parentheses, foo 8, left parentheses, n minus 1, right parentheses, plus, foo 8, left parentheses, n minus 2, right parentheses, right parentheses, semicolon. Line 9: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, int, if, else. Line 1: public static void foo 9, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, n, equals, equals, 0, right parentheses. Line 5, indented twice: System dot out dot print l n, left parentheses, double quotes, done, double quotes, right parentheses, semicolon. Line 6, indented once: else. Line 7, indented twice: foo 9, left parentheses, n forward slash 2, right parentheses, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, void, int, if, else. Line 1: public static void foo 10, left parentheses, int n, comma, int p, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n and p are guaranteed to be greater than or equal to 1. Line 4, indented once: if, left parentheses, p greater than or equal to n, right parentheses. Line 5, indented twice: System dot out dot print l n, left parentheses, double quotes, done, double quotes, right parentheses, semicolon. Line 6, indented once: else. Line 7, indented twice: foo 10, left parentheses, n, comma, 2 asterisk p, right parentheses, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords:

public, static, void, int, if, else, return. Line 1: public static void foo 11, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, n, equals, equals, 0, right parentheses. Line 5, indented twice: return 0, semicolon. Line 6, indented once: else. Line 7, indented twice: return, left parentheses, 5 plus 2 asterisk foo 11, left parentheses, n minus 1, right parentheses, right parentheses, semicolon. Line 8: right brace.

Back to Code

Fib, left parentheses, 1, right parentheses, equals, Fib, left parentheses, 2, right parentheses, equals, 1. Fib, left parentheses, n, right parentheses, equals, Fib, left parentheses, n minus 1, right parentheses, plus, Fib, left parentheses, n minus 2, right parentheses.

Back to Equation

H T M L code converted to a tree by a web browser. The root node is h t m l. This node has the left child, head and the right child, body. The head nod has the left child, title. The body node has the left child, p and the right child, o l. The o l node has the three l i child nodes.

Back to Figure

A tree that stores integers. The root node is 33. This node has the three child nodes, 20, 54, and 21. The node 20 has the child nodes 34 and 87. The node 34 has the child node, 17. The node 87 has the child nodes, 25, 44, 22, and 78. The node 22 has the child node, 99. The node 21 has the child node, 84.

Back to Figure

A binary tree storing integers. The root node is 33. The root node has the child nodes, 20 and 21. The node 20 has the child nodes, 34 and 87. The node 34 has the child node 17. The node 87 has the child nodes, 25 and 44. The node 21 has the child node, 84.

Back to Figure

A binary tree storing integers. Root node is 20. It has the next sibling, 54 and left child, 34.

Back to Figure

A binary tree storing integers. The root node is 33. It has a left child, 20. The node 20 has a left child, 34 and a next sibling, 54. The node 54 has a next sibling, 21. The node 34 has the left child, 17 and the next sibling 87. The node 87 hast he left child 25. The node 25 has the next sibling 44. The node 44 has the next sibling 22. The node 22 has the left child, 99 and the next sibling 78. The node 21 has the left child, 84.

Back to Figure

A complete binary tree. The root node is 33. The node 33 has the child nodes, 20 and 21. The node 20 has the child nodes, 34 and 87. The node 21 has the child nodes, 62 and 84. The node 34 has the child nodes, 3 and 17. The node 87 has the child nodes, 25 and 44. The node 62 has the child node, 10.

Back to Figure

A full binary tree. The root node is 33. The node 33 has the child nodes, 20 and 21. The node 20 has the child nodes, 34 and 87. The node 21 has the child nodes, 62 and 84. The node 34 has the child nodes, 3 and 17. The node 87 has the child nodes, 25 and 44. The node 62 has the child nodes, 10 and 70. The node 84 has the child nodes, 55 and 92.

Back to Figure

A height-unbalanced binary tree. The root node of this binary tree is 33. The node 33 has the child nodes, 20 and 21. The node 20 has the child nodes, 34 and 87. The node 21 has the child node, 84. The node 34 has the child node, 17. The node 87 has the child node, 25. The node 84 has the child node, 44.

Back to Figure

A diagram that explains how the attach Left and attach Right methods work. The root node is shows. The attach Left method takes the binary tree parameter named b t which may contain 0 or more elements and attaches its root to the left child of root. The attach Right method takes the binary tree parameter named b t which may contain 0 or more elements and attaches its root to the right child of root.

Back to Figure

A example of pre order, in order, and post order traversals in a tree that is performed by walking counterclockwise around the tree. The following binary tree is shown. The root node is 33. The node 33 has the children, 20 and 21. The node 20 has the children, 34 and 87. The node 21 has the child 84. The node 34 has the child, 17. The node 87 has the children, 25 and 44. The pre order, in order, and post order traversals in this tree happens in the following order. 33, 20, 34, 17, 20, 87, 25, 87, 44, 87, 20, 33, 21, and 84.

Back to Figure

A node is visited on three occasions. 1. Pre order. 2. In order. 3. Post order. 34, 17, and 34.

Back to Figure

The output of the program in Example 15.5. Pre order: 33, 20, 34, 17, 87, 25, 44, 21, 84. In order: 34, 17, 20, 25, 87, 44, 33, 21, 84. Post order: 17, 34, 25, 44, 87, 20, 84, 21, 33.

Back to Figure

A binary search tree in which values on the left are smaller than 50 and the value son the right are larger than 50. The root node in the binary tree is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child node, 25 and 44.

Back to Figure

A binary tree that is not a binary search tree. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 25. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 25 has the child nodes, 36 and 44.

Back to Figure

The number 44 is searched in a binary search tree. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 25 and 44. The number 44 is located with the following traversals. 50, 20, 36, 44.

Back to Figure

A binary search tree that is similar to a linked list. The root node is 1. It has the child node, 2. The node 2 has the child node, 3. The node 3 has the child node, 4. The node 4 has the child node, 5.

Back to Figure

The number 60 is inserted in a binary search tree. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 25 and 44. The following traversals occur after which the number 60 is inserted. 50, 66.

Back to Figure

Insertions that are done in a binary search tree. The root node is 50. The node 20 is inserted as a child of the node 50. Node 36 is inserted as a child of node 20. Node 66 is inserted as a child of node 50. Node 25 is inserted as a child of node 36. Node 5 is inserted as a child of node 20. Node 17 is inserted as a child of node 5. Node 84 is inserted as a child of node 66. Node 44 is inserted as a child of node 36.

Back to Figure

The resulting binary search tree after the number 25 is deleted from it. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 44.

Back to Figure

The resulting binary search tree after the number 5 is deleted from it. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 17 and 36. The node 66 has the child node, 84. The node 36 has the child nodes, 25 and 44.

Back to Figure

The two candidate replacement values when 50 is deleted from the binary search tree in Figure 15.13 The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 44. The largest value on the left of 50 is 44, and the smallest value on the right of 50 is 66.

Back to Figure

The largest value in the left subtree is located. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 44. The following traversals are done to locate, 44. 50, 30, 36, 44.

Back to Figure

The smallest value in the right subtree is located. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 44. The following traversals are done to locate, 66. 50, 66.

Back to Figure

The resulting tree after 50 is deleted from it using the first scenario. The root node is 44. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child node, 25.

Back to Figure

The resulting tree after 50 is deleted from it using the second scenario. The root node is 66. It has the child nodes, 20 and 84. The node 20 has the child nodes, 5 and 36. The node 5 has the child node, 17. The node 36 has the child nodes, 25 and 44.

Back to Figure

The steps in deleting the number 50 stored in a node with two children. The instance n d represents the following binary search tree. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 25 and 44. 44 is the largest value on the left side. 50 is changed to 44. 44 is deleted in the subtree whose root contains 20.

Back to Figure

The number 5 is deleted from the binary search tree. The binary search tree has the following nodes. The root node is 50. It has the child nodes, 20 and 66. The node 20 has the child nodes, 5 and 36. The node 66 has the child node, 84. The node 5 has the child node, 17. The node 36 has the child nodes, 25 and 44. 5 is deleted. An edge points from 50 to 20. The edge from 20 is set to 17. The links between 20 to 5 and 5 to 17 are reset when 5 is deleted.

Back to Figure

The output of the program in Example 15.7. Pre order: 50, 20, 5, 17, 36, 25, 44, 66, 84. In order: 5, 17, 20, 25, 36, 44, 50, 66, 84. Post order: 17, 5, 25, 44, 36, 20, 84, 66, 50. Deleting 50. Pre order: 44, 20, 5, 17, 36, 25, 66, 84. In order: 5, 17, 20, 25, 36, 44, 66, 84. Post order: 17, 5, 25, 36, 20, 84, 66, 44. Deleting 8. Pre order: In order: Post order:

Back to Figure

The resulting array when the binary search tree is unloaded by traversing in order. The index positions and values of the resulting array are listed further. 0, 5; 1, 17; 2, 20; 3, 25; 4, 36; 5, 44; 6, 50; 7, 66; 8, 84.

Back to Figure

The balanced binary search tree that is built from the array. The root node is 36. It has the child nodes, 17 and 50. The node 17 has the child node, 5 and 20. The node 50 has the child nodes, 44 and 66. The node 66 has the child node, 84.

Back to Figure

The output of the program in Example 15.8. Pre order: 5, 17, 20, 25, 36, 44, 50, 66, 84. In order: 5, 17, 20, 25, 36, 44, 50, 66, 84. Post order: 84, 66, 50, 44, 36, 25, 20, 20, 17, 5. After rebuilding the tree. Pre order: 36, 17, 5, 20, 25, 50, 44, 66, 84. In order: 5, 17, 20, 25, 36, 44, 50, 66, 84. Post order: 5, 25, 20, 17, 44, 84, 66, 50, 36.

Back to Figure

The inheritance hierarchy for J Frame is as follows. Object. Component. Container. Window. Frame. J Frame.

Back to Figure

A window that is generated by the code in Example 16.1. The window has the following text in the title bar. A Shell G U I Application. The window has minimize, maximize, and close buttons.

Back to Figure

The inheritance hierarchy for some G U I classes. J Radio Button and J Check Box inherit from J Toggle Button. J Button and J Toggle Button inherit from Abstract Button.

Abstract Button, J List and J Combo Box inherit from J Component. J Password Field inherits from J Text Field. J Text Field and J Text Area inherit from J Text Component. J Label and J Text Component inherit from J Component. J Component inherits from Container. Container inherits from Component. Component inherits from Object. Object is the class that is at the top of the hierarchy.

Back to Figure

The window that is displayed on running Example 16.2. A window is displayed with the following text in the title bar. “What's for dinner?” Inside the window is the following label. Sushi tonight? A photograph of sushi is displayed to the right of the label. A tooltip is displayed with the following text. photo of sushi.

Back to Figure

Hierarchy of the Event class. Mouse Event inherits from Input Event. Input Event inherits from Component Event. Action Event, Item Event, and Component Event inherit from A W T Event. List Selection Event and A W T Event inherit from Event Object. Event Object inherits from Object.

Back to Figure

Running the program in Example 16.3. A window is displayed with the following text in the title bar. Login Screen. It has two input fields with the labels, Enter I d and Enter password. A warning message is displayed below the input boxes stating that illegal login will be punishable by law. In this window, the i d is entered as wrong I D and four question marks are entered as the password. In one more attempt, open is entered as the i d and six question marks are entered as the password.

Back to Figure

Running the program in Example 16.7. A window is displayed with the text, “Simple Math” in the title bar. An input field is present in the window with the label, Enter a number. There are two buttons below the input field with the labels, Square and Cube. The Square button has been clicked. Below the buttons, the result is displayed as 16.

Back to Figure

The program in Example 16.5 is executed. It displays a window with the following text in the title bar. Selecting a color. There are three radio buttons with the labels red, green, and blue. Below, the radio buttons is the following text. Watch my background. The background of this text changes according to the radio button that is selected.

Back to Figure

The program in Example 16.6 is executed. The program displays a window with the following text in the title bar. Selecting a color. Three checkboxes are displayed in the window with the labels, red, green, and blue. The red and green checkboxes are checked. Below the checkboxes, the following text is displayed with a background color. Watch my background.

Back to Figure

A G U I window with a circuit displayed in it. The window shows an electrical circuit with a power source, light bulb, and a switch. Two buttons are present above the circuit, labeled Open and Close. The Open button has been clicked. The switch in the circuit is displayed in the open position.

Back to Figure

A G U I window with a circuit displayed in it. The window shows an electrical circuit with a power source, light bulb, and a switch. Two buttons are present above the circuit, labeled Open and Close. The Close button has been clicked. The switch in the circuit is displayed in the close position. The light bulb is displayed in yellow, since it is alight.

Back to Figure

The window that is displayed when the program in Example 16.8 is executed. The window displays the following text in the title bar. Food samplings of various countries. A J Combo Box is present in the window. The selection in the J Combo Box is Greece. Next to the combo box is an image.

Back to Figure

U M L diagram for the classes Sub Hunt and Sub Hunt View Controller. Sub Hunt has a composition relationship with Sub Hunt View Controller. Mouse Handler has a composition relationship with Sub Hunt View Controller. Mouse Handler inherits from Mouse Adapter. Sub Hunt has the following data members and methods. The data members are the following. DEFAULT underscore GAME underscore SIZE with i n t data type. SIDE with i n t data type. game Size with i n t data type. x C t r with i n t data type. y C t r with i n t data type. status with String data type. hit with boolean data type. The methods are the following. Sub Hunt with i n t parameter. get Status with String return type. Get Game Size with i n t return type. is Hit with boolean return type. play with two i n t parameters and void return type. draw with Graphics, and two i n t parameters and void return type. Sub Hunt View Controller has the following data members and methods. The data members are the following. sub with Sub Hunt data type. x with i n t data type. y with i n t data type. game Started with boolean data type. insets with Insets data type. m h with Mouse Handler data type. The methods are the following. Sub Hunt View Controller with Sub Hunt parameter. paint with Graphics parameter and void return type. Mouse Handler has the following method. mouse Clicked with Mouse Event parameter and void return type. The Mouse Adapter class is present in the package java dot a w t dot event.

Back to Figure

A J Frame is shown in gray with the sub hunt game rectangle inside it in orange. The top, right, bottom, and left boundaries between the rectangle and the J Frame are indicated.

Back to Figure

The sub hunt game program executing. A window is displayed with the following text in the title bar. Sunk! Many blue dots are displayed on the screen.

Back to Figure

U M L diagram for the Treasure Hunt game. The following details are shown in the diagram. Treasure Hunt has Treasure Hunt View Controller. Treasure Hunt View Controller implements Mouse Motion Listener in the packet java, dot, a w t, dot event package. Treasure Hunt class has the following data members. DEFAULT underscore GAME underscore SIZE constant of i n t data type. SIDE constant of i n t data type. game Size of i n t data type. x C t r of i n t data type. y C t r of i n t data type. status of String data type. game Over of boolean data type. The following methods are also present. Treasure Hunt with i n t parameter. get Status with String return type. get Game Size with i n t return type. is Game Over with boolean return type. play with two i n t parameters and void return type. draw with a Graphics and two i n t return types. It has a void return type. Treasure Hunt View Controller class has the following data members. hunt of Treasure Hunt data type. x of i n t data type. y of i n t data type. insets of Insets data type. The following methods are also present. Treasure Hunt View Controller with Treasure Hunt parameter. mouse Moved with Mouse Event parameter and void return type. mouse Dragged with Mouse Event parameter and void return type. paint with Graphics parameter and void return type.

Back to Figure

The Play Treasure Hunt program executing. A window is displayed with the word, “Play!” displayed in the title bar. The word, warm is displayed in the window with the mouse pointer on it. The user is getting close to the treasure.

Back to Figure

The Play Treasure Hunt program executing. A window is displayed with the word, “Play!” displayed in the title bar. The user has found the treasure. Inside the window, a red box is displayed with three dollar symbols under the mouse pointer indicating that the treasure has been found.

Back to Figure

The program in example 16.15 runs and displays a window with a chess board in white and red grids. In the title bar, the following text is displayed. Click a square to display its position. The following grid positions are displayed. A 8. b 2. b 5. c 3. d 7. e 4. f 2. f 8. h 1.

Back to Figure

A window displaying the winning position of a 3-by-3 tile puzzle game. The window displays tiles in a 3 by 3 grid. The tiles are numbered from 1 to 8 from top to bottom and left to right. The last tile in the bottom row is blank.

Back to Figure

U M L Diagram for Tile Puzzle and Tile Puzzle View Controller. The following details are shown in the diagram. Tile Puzzle has Tile Puzzle View Controller. Grid Button has Tile Puzzle View Controller. Button Handler is nested in Tile Puzzle View Controller. Grid Button implements J Button. Tile Puzzle class has the following data members. tiles with data type of String array. side with i n t data type. empty Row with i n t data type. empty C o l with i n t data type. The following methods are also present. Tile Puzzle with i n t parameter. set Up Game with void return type. get Side with i n t return type. get Tiles with String array return type. try To Play with two i n t parameters and boolean return type. possible To Play with two i n t parameters and boolean return type. won with boolean return type. Tile Puzzle View Controller has the following data members. game with Tile Puzzle data type. contents with Container data type. squares with Grid Button array data type. The following methods are also present. Tile Puzzle View Controller with Tile Puzzle data type. set Up Game G U I with void return type. Up data with void return type. Grid Button class has the following data members. row with i n t data type. column with i n t data type. The following methods are present. Grid Button with a String and two i n t parameters. get Row with i n t return type. get Column with i n t return type. set Row with i n t parameter and void return type. set Column with i n t parameter and void return type. Button Handler class has the following method. action Performed with Action Event parameter and void return type. J Button is a class in the java x dot swing package.

Back to Figure

A window displays tile puzzle game. In the title bar, the following text is displayed. The Tile Puzzle Game. The window displays tiles in a 3 by 3 grid. The first row of tiles are numbered 1 to 3. The second row of tiles are numbered 8, 5, and blank. The third row of tiles are numbered 8, 7, and 4.

Back to Figure

A rectangular box displays the areas in Border Layout. The areas are North, West, Center, East, and South representing geographical directions in the box.

Back to Figure

The U M L Diagram for Classes of an application. The following details are shown in the diagram. Border Layout View has R G B Color Mixer Controller. R G B Color Mixer Controller implements Action Listener. One more class is R G B Color Mixer. Border Layout View class has the following data members. center with J Label data type. north with J Button data type. east with J Button data type. south with J Button data type. west with J Button data type. The following methods are also present. Border Layout View. get North with J Button return type. get East with J Button return type. get South with J Button return type. get West with J Button return type. get Center with J Label return type. R G B Color Mixer Controller class has the following data members. model with R G B Color Mixer data type. view with Border Layout View data type. The following methods are also present. R G B Color Mixer View with R G B Color Mixer and Border Layout View parameters. action Performed with Action Event parameter and void return type. update View with void return type. R G B Color Mixer has the following data members. POSITION underscore CHANGE constant with i n t data type. POSITION underscore RED constant with i n t data type. POSITION underscore GREEN constant with i n t data type. POSITION underscore GREEN constant with i n t return type. POSITION underscore BLUE constant with i n t data type. delta with i n t data type. color with Color data type. The following methods are also present. R G B Color Mixer with i n t parameter. get Color with Color return type. invert Delta with void return type. add To Red with void return type. add To Green with void return type. add To Blue with void return type. get Method Label with i n t parameter and String return type. get Title with String return type. to String with String return type.

Back to Figure

The Mix Colors application executing. A window is displayed with the text, “Start Mixing Colors” displayed in the title bar. Inside the window, in the north direction is a button with the label, “CHANGE DIRECTION.” In the east, west, and south directions are the buttons with the labels, RED, BLUE, and GREEN. In the center, a color shade is displayed with the following label. r equals 175. g equals 135. b equals 155.

Back to Figure

A window that is displayed when the Color Frequency game executes. The window has the following text displayed in the title bar. What is the most frequent color? Inside the window, in the west side, there are three buttons laid out in a single column with the labels, RED, GREEN, and BLUE. The rest of the window features several squares colored, red, blue, and green.

Back to Figure

The underlying nested layout for the display in a program. The window is divided into the west and center regions. In the west region is a J Panel managed by a 3 by 1 Grid Layout. In the center is a J Panel managed by an 8 by 8 Grid Layout.

Back to Figure

The U M L diagram for the various classes and interface in this application. The diagram shows the following information. Color Grid Game Controller has Bordered Label Grid View. Color Grid Game Controller has Color Grid Game. Color Grid Game Controller implements Action Listener. Color Frequency Game implements Color Grid Game. The interface Action Listener is from the package java dot a w t dot event. Color Grid Game Controller class has the following data members. model with Color Grid Game data type. View with Bordered Label Grid View data type. The following methods are also present. Color Grid Game Controller with Color Grid Game and Bordered label Grid View parameters. set Up Game with void return type. set Up Labels with void return type. set Up Buttons with void return type. action Performed with Action Event data type and void return type. Bordered Label Grid View class has the following data members. button Panel with J Panel data type. buttons with J Button array data type. grid with J Panel data type. labels with J Label two dimensional array data type. The following methods are also present. Bordered Label Grid View with two i n t parameters. set Button Text with an i n t and String parameter with void return type. set Button Listener with i n t and Action Listener parameters and void return type. set Label Background with two i n t and Color parameters with void return type. Color Grid Game interface has the following methods. get Title with String return type. get Size with i n t return type. get Number Of Colors with i n t return type. get Label with i n t parameter and String return type. get Index with String parameter and i n t return type. is Correct with i n t parameter and boolean return type. get Grid Color with two i n t parameters and Color return type. Color Frequency Game class has the following data members. DEFAULT underscore SIZE constant with i n t data type. grid Colors with Color two dimensional array data type. coloring Colors with Color data type. counts with int array data type. labels with String array data type. The following methods are also present. Color Frequency Game with i n t, Color array, and String array parameters. fill Grid With Colors with void return type. highest Count with i n t return type. get Title with String return type. get Size with i n t return type. get Number Of Colors with i n t return type. get Label with i n t return type. get Label with i n t parameter and String return type. is Correct with i n t parameter and boolean return type. get Grid Color with two i n t parameters and Color return type.

Back to Figure

In the Color Frequency game, the user has to find the more frequent color in a grid of colors. Red, Green, and Blue buttons are given for the user to select an answer. The user clicks on the button BLUE and the program displays a message box with the following text and an O K button. You won.

Back to Figure

The Tile Puzzle game executing. A window is displayed with the following text in the title bar. Practicing layout managers. The following label is displayed at the bottom of the window. Have fun playing this Tile Puzzle game.

Back to Figure

The Tile Puzzle game executing. A window is displayed with the following text in the title bar. Practicing layout managers. The following label is displayed at the bottom of the window. Have fun playing this Tile Puzzle game. A row of buttons is present for the user to make a selection for the number of tiles. The buttons have the following labels. 3 by 3. 4 by 4. 5 by 5. The user has clicked on the 3 by 3 button. 3 rows of 3 tiles are displayed in a grid numbered from 1 to 8 randomly along with one blank tile.

Back to Figure

The root Node is labeled Object. Node class inherits from the Object Class. Parent class inherits from the Node class. Region class inherits from the Parent class. Control class inherits from the Region class. The 4 classes inheriting from the Control class are as follows: Text Input Control, Labeled, Slider, Combo Box Base, left angled bracket, uppercase t, right angled bracket. The Text Field class inherits from the Text Input Control class. The Button Base and Label classes inherit from the Labeled class. The Combo Box, left angled bracket, uppercase t, right angled bracket, class inherits from the Combo Box Base, left angled bracket, uppercase t, right angled bracket, class. The Text Field Class inherits from the Text Input Control class. The classes which inherit from the Labeled class are as follows: Button Base and Label. The class which inherits from the Combo Box Base, left angled bracket, uppercase t, right angled bracket, class is, Combo Box, left angled bracket, uppercase t, right angled bracket. The classes which inherit from the Button Base class are as follows: Button, Check Box, Toggle Button. The class which inherits from the Toggle Button class is Radio Button.

Back to Figure

The root Node is labeled Object. Node class inherits from the Object Class. Parent class inherits from the Node class. Region class inherits from the Parent class. Pane class inherits from the Region class. The classes inheriting from the Pane class are as follows: Border Pane, Grid Pane, H Box, Stack Pane, and V Box.

Back to Figure

The window has a caption which reads: Sushi tonight, question mark. A photo below the caption displays a plate of Sushi.

Back to Figure

The window has a text label, a text box, 2 buttons and another text label below the second button. The first text label reads: Enter a number. The cursor is within the text box. The buttons are labeled Square and Cube, respectively. The second text label reads: Result.

Back to Figure

The window has a text label, a text box, 2 buttons and another text label below the second button. The first text label reads: Enter a number. The entry within the text box reads: 3. The buttons are labeled Square and Cube, respectively. The button labeled cube is selected. The second text label reads: Result. The text displayed at the bottom of the window reads: 27.0.

Back to Figure

The window has 3 radio buttons and a caption with a red background. The radio buttons are labeled red, green, and blue. The radio button labeled red is selected. The caption reads: Watch my background.

Back to Figure

The window has 3 check boxes and a text label. The check boxes are labeled red, green and blue. The text label reads: Watch my background.

Back to Figure

The window has 2 buttons and a circuit diagram. The buttons are labeled OPEN and CLOSE. The circuit diagram has a Light bulb and an open switch in series with a Power source. The button labeled OPEN is selected.

Back to Figure

The window has 2 buttons and a circuit diagram. The buttons are labeled OPEN and CLOSE. The circuit diagram has a Light bulb and a closed switch in series with a Power source. The button labeled CLOSE is selected. The light bulb glows.

Back to Figure

The window has a drop down selection box and an image. The selected option is labeled France. The image displays a plate containing French cuisine.

Back to Figure

The window displays a color image and a grayscale image. A scale at the bottom of the window ranges from 0 to 0.33. The slider on the scale is set to 0.165.

Back to Figure

The window displays a chessboard. The white squares in the first row and the first, fifth, and seventh columns are marked a 8, e 8, and g 8, respectively. The red squares in the first row and the sixth and eighth columns are marked f 8 and h 8, respectively. The white square in the second row and second column is labeled b 7. The red square in the second row and third column is marked c 7. The red square in the third row and fourth column is marked d 6. The white square in the fourth row and sixth column is labeled f 5. The white square in the sixth row and second column is marked b 3. The red squares in the eighth row and the first and third columns are marked a 1 and c 1, respectively. The white squares in the eighth row and the second and eighth columns are marked b 1 and h 1, respectively.

Back to Figure

The window displays a chessboard. The white square in the first row and first column is marked a 8. The white square in the third row and fifth column is marked e 6. The red square in the sixth row and third column is marked c 3. The red square in the seventh row and eighth column is marked h 2. The white square in the eighth row and eighth column is marked h 1.

Back to Figure

The window has tiles arranged in 3 rows and 3 columns. The tiles in the first row are marked 1, 2, and 3. The tiles in the second row are marked 4, 5, and 6. The tiles in the third row are marked 7, 8, and blank.

Back to Figure

The classes shown in the diagram are titled Tile Puzzle, Grid Button, Tile Puzzle View Controller, and Button Handler. The attributes of the Tile Puzzle class are as follows: tiles, colon, Strings, left square bracket, right square bracket, left square bracket, right square bracket, side, colon, int, empty Row, colon, int, empty Col, colon, int. The methods of the Tile Puzzle class are as follows: Tile Puzzle, left parentheses, right parentheses, set Up Game, left parentheses, right parentheses, colon, void, get Side, left parentheses, right parentheses, colon, int, get Tiles, left parentheses, right parentheses, colon, String, left square bracket, right square bracket, left square bracket, right square bracket, try To Play, left parentheses, int, comma, int, right parentheses, colon, boolean, possible To Play, left parentheses, int, comma, int, right parentheses, colon, boolean, won, left parentheses, right parentheses, colon, boolean. The attributes of the Grid Button class are as follows: row, colon, int, column, colon, int. The methods of the Grid Button class are as follows: Grid Button, left parentheses, String, comma, int, comma, int, right parentheses, get Row, left parentheses, right parentheses, colon, int, get Column, left parentheses, right parentheses, colon, int, set Row, left parentheses, int, right parentheses, colon, void, set Column, left parentheses, int, right parentheses, colon, void. The attributes of the Tile Puzzle View Controller class are are follows: game, colon, Tile Puzzle, squares, colon, Grid Button, left square bracket, right square bracket, left square bracket, right square bracket.

The methods of the Tile Puzzle View Controller Class are as follows: Tile Puzzle View Controller, left parentheses, Tile Puzzle, right parentheses, set Up Game G U I, left parentheses, right parentheses, colon, void, update, left parentheses, right parentheses, colon, void, show Message Dialog, left parentheses, String, comma, String, right parentheses, colon, void. Lines with a shaded diamond at the end are drawn from the Tile Puzzle and the Grid Button classes to the Tile Puzzle View Controller class. The method in the Button Hander class is handle, left parentheses, Action Event, right parentheses, colon, void. A line terminating in a circle with a plus symbol within it is drawn from the Button Handler class to the Tile Puzzle View Controller class. An arrow is drawn from the Grid Button class to Button which is in the java f x dot scene dot control package.

Back to Figure

The window displays 9 tiles arranged in 3 rows and 3 columns. The labels of the tiles in the first row are 1, 2, and 3. The labels of the tiles in the second row are 6, 5, and blank. The labels of the tiles in the third row are 8, 7, and 4.

Back to Figure

A large rectangle is subdivided into 3 smaller rectangles from top to bottom. The first and third rectangles are labeled top and bottom, respectively. The second rectangle is subdivided into 3 smaller rectangles from left to right and they are labeled, left, center, and right, respectively.

Back to Figure

The window has 2 panes. The first pane has 6 buttons labeled Fade, Rotate, Scale, Combine Animations, Start Translate, and Stop Translate. The last button is deactivated. The second pane displays the image of a sprite.

Back to Figure

The Color Frequency Game Figure A shows the Color Frequency game executing. A window is displayed with the following text in the title bar. What is the most frequent color? In the left side of the window are three buttons with the labels RED, GREEN, and BLUE laid out in a single column. Next to the buttons is a color grid of with red, green, and blue squares.

Back to Figure

The underlying nested layout used in the Color Frequency game. Figure B shows the underlying nested layout in the Color Frequency game. In the LEFT side of the window is a V Box with 3 buttons. In the CENTER is a Grid Pane with 64 buttons organized in 8 rows and 8 columns.

Back to Figure

The U M L diagram for the Color Frequency Game application. The diagram shows the following details. Color Grid Game Controller has Bordered Label Grid View. Color Grid Game Controller has Color Grid Game. Color Frequency Game implements Color Grid Game. Color Grid Game Controller implements Event Handler. Color Grid Game Controller has the following data members. model with Color Grid Game data type. view with Bordered Label Grid View data type. This class has the following methods. Color Grid Game Controller with Color Grid Game and Bordered Label Grid View parameters. set Up Game with void return type. set Up Labels with void return type. set Up Buttons with void return type. handle with Action Event parameter and void return type. Bordered Label Grid View has the following data members. button Panel with V Box data type. buttons with Button array data type. grid with Grid Pane data type. labels with Label two dimensional array. This class has the following methods. Bordered Label Grid View with two i n t parameters. set Button Text with i n t and String parameters and void return type. set Button Listener with i n t and Event Handler, left angle bracket, Action Event, right angle bracket parameters and void return type. set Label Background with two i n t and one String parameters with void return type. Color Grid Game interface has the following methods. get Title with String return type. get Size with i n t return type. get Number Of Colors with i n t return type. get Label with i n t parameter and String return type. get Index with String parameter and i n t return type. is Correct with i n t parameter and boolean return type. get Grid Hex Color with two i n t parameters and String return type. Color Frequency Game class has the following data members. DEFAULT underscore SIZE constant with i n t data type. grid Colors with Color two dimensional array data type. coloring Colors with Color array data type. counts with i n t array data type. labels with String array data type. This class has the following methods. Color Frequency Game with i n t, Color array, and String array parameters. fill Grid With Colors with void return type. get Size with i n t return type. get Number Of Colors with i n t return type. get Number Of Colors with i n t return type. get Grid Hex Color with two i n t parameters and String return type. to Hex with i n t parameter and String return type. highest Count with i n t return type. is Correct with i n t parameter and boolean return type. get Title with String return type. get Label with i n t parameter and String return type. get Index with String parameter and i n t return type. Interface Event Handler, left angle bracket, Action Event, right angle bracket is present in the java f x dot event package. Figure 17.2 Chapter 17 In the Color Frequency game, the user has to find the more frequent color in a grid of colors. Red, Green, and Blue buttons are given for the user to select an answer. The user clicks on the button GREEN and the program displays a message box with the following text and an O K button. You won.

Back to Figure

U M L diagram for the Sub Hunt game. The following details are shown in the diagram. Sub Hunt has Sub Hunt View Controller. Sub Hunt class has the following data members. DEFAULT underscore GAME underscore SIZE constant with i n t data type. SIDE constant with i n t data type. game Size with i n t data type. x C t r with i n t data type. y C t r with data type. status with String data type. h i t with boolean data type. The following methods are also present. Sub Hunt with i n t parameter. get Game Size with i n t return type. get Status with i n t return type. is Hit with boolean return type. play with two i n t parameters and void return type. draw with Graphics Context and two i n t parameters, and void return type. Sub Hunt View Controller class has the following data members. hunt with Sub Hunt data type. stage with Stage data type. g c with Graphics Context data type. The following methods are also present. Sub Hunt View Controller with Sub Hunt, Stage, and two i n t parameters. handle Mouse Event with Mouse Event parameter and void return type. handle Touch Event with Touch Event parameter and void return type. play with two i n t parameters and void return type.

Back to Figure

The Sub Hunt game running in a window. A submarine is indicated by a black colored graphic and there are other blue dots in the window.

Back to Figure

U M L diagram for the Sub Hunt game. The following details are shown in the diagram. Treasure Hunt has Treasure Hunt View Controller. Treasure Hunt View Controller implements Event Handler. The Treasure Hunt class has the following data members. DEFAULT underscore GAME underscore SIZE constant with i n t data type. SIDE constant with i n t data type. game Size with i n t data type. x C t r with i n t data type. y C t r with i n t data type. status with String data type. game Over with boolean data type. This class has the following methods as well. Treasure Hunt with i n t parameter. get Game Size with i n t return type. is Game Over with boolean return type. play with two i n t parameters and void return type. draw with a Graphics and two i n t parameters and void return type. The Treasure Hunt View Controller class has the following data members. width with i n t data type. height with i n t data type. hunt with Treasure Hunt data type. g c with Graphics Context data type. This class has the following methods as well. Treasure Hunt View Controller with Treasure Hunt and two i n t parameters. handle with Input Event parameter and void return type.

Back to Figure

The user getting close to the treasure in the Play Treasure Hunt game. A window is displayed with the word, “Play!” displayed in the title bar. The word, warm is displayed in the window with the mouse pointer on it.

Back to Figure

The user finding the treasure in the Play Treasure Hunt game. A window is present with the word, “Thank you for playing” displayed in the title bar. Inside the window, a red box is displayed with three dollar symbols under the mouse pointer indicating that the treasure has been found.

Back to Figure

A program that displays a pie chart for monthly expenses. A window with a pie chart is shown. In the title bar, the following text is displayed. Pie Chart for Monthly Expenses. The pie chart shows the following details. Rent: 50 percent. Food: 27 percent. Phone: 5 percent. Entertainment: 11 percent. Utilities: 7 percent.

Back to Figure

A bar chart for stocks and bonds displayed using the first set of values for stocks. The chart is labeled, “Next Scenario.” The following details are indicated in the bar chart. 2020: Bonds: 100; Stocks, 100. 2021: Bonds: 102; Stocks, 108. 2022: Bonds: 106; Stocks, 116. 2023: Bonds: 108; Stocks, 122.

Back to Figure

A bar chart for stocks and bonds displayed using the second set of values for stocks. The chart is labeled, “Next Scenario.” The following details are indicated in the bar chart. 2020: Bonds: 100; Stocks, 98. 2021: Bonds:

104; Stocks, 100. 2022: Bonds: 106; Stocks, 102. 2023: Bonds: 108; Stocks, 104.

Back to Figure

The Simple Math application running. A window is displayed with the text “ Simple Math” listed in the title bar. A label is present with the text, “Enter a number.” A text field is present for input. Below the text field are two buttons. One for Square and the other for Cube. Below these buttons is a label with the text, “Result.” The Cube button changes color to green when the mouse hovers over it.

Back to Figure

The Simple Math application running. A window is displayed with the text “ Simple Math” listed in the title bar. A label is present with the text, “Enter a number.” A text field is present for input. Below the text field are two buttons. One for Square and the other for Cube. Below these buttons is a label with the text, “Result.” The number 3 is entered in the text field and the Cube button is clicked. This prints the number 27.0 below the result label.

Back to Figure

A window displayed for the Tile Puzzle Game. A window is shown with the text “Practice Nested Layouts” displayed in the title bar. The window is empty. In the bottom left corner of the window, a label is displayed with the text “Have fun playing this Tile Puzzle game.”

Back to Figure

A window displayed for the Tile Puzzle Game. A window is shown with the text “Practice Nested Layouts” displayed in the title bar. Inside the window there are three labels displayed in the top row with the following text. 3 by 3. 4 by 4. 5 by 5. Below this row there are three rows and three columns of square buttons with numbers displayed in them. In the first row are the numbers 8, 7, and 6. In the second row are the numbers 5, 4, and 3. In the third row are the numbers 2, 1, and blank.

Back to Figure

The table has 2 columns labelled Memory Unit and Size. The row entries are as follows.
Row 1. Memory Unit: K B or K bytes or kilobytes. Size: About 1000 bytes, left parentheses, exactly 2 to the power of 10 or 1024 bytes, right parentheses.
Row 2. Memory Unit: M B or M bytes or megabytes. Size: About 1 million bytes, left parentheses, exactly 2 to the power of 20 or 1,048,576 bytes, right parentheses.
Row 3. Memory Unit: G B or G bytes or gigabytes. Size: About 1 billion bytes, left parentheses, exactly 2 to the power of 30 or 1,073,741,824 bytes, right parentheses.
Row 4. Memory Unit: T B or T bytes or terabytes. Size: About 1 trillion bytes, left parentheses, exactly 2 to the

power of 40 or 1.09951 times 10 to the power of 21 bytes, right parentheses.

Back to Table

The table has 6 columns labelled Device, Location, Type, Speed, Capacity in M B, and cost per K B. The row entries are as follows.
Row 1. Device: L 1 cache. Location: on-chip. Type: S R A M. Speed: Very fast. Capacity in M B: Very small. Cost per K B: Very high.
Row 2. Device: L 2 cache. Location: off-chip. Type: S R A M. Speed: Fast. Capacity in M B: Small. Cost per K B: High.
Row 3. Device: Memory. Location: off-chip. Type: D R A M. Speed: Moderate. Capacity in M B: Moderate. Cost per K B: Moderate.
Row 4. Device: Hard disk. Location: Separate. Type: Disk media. Speed: Slow. Capacity in M B: Large. Cost per K B: Small.

Back to Table

The equation reads: 359, equals, 3 times 10 to the power of 2, plus, 5 times 10 to the power of 1, plus, 9 times 10 to the power of 0.

Back to Code

The equation reads: 11011, equals, 1 times 2 to the power of 4, plus, 1 times 2 to the power of 3, plus, 0 times

2 to the power of 2, plus, 1 times 2 to the power of 1, plus, 1 times 2 to the power of 0.

Back to Code

The table has 2 columns labelled Decimal and Binary.
The row entries are as follows.
Row 1. Decimal: 0. Binary: 0 0 0 0.
Row 2. Decimal: 1. Binary: 0 0 0 1.
Row 3. Decimal: 2. Binary: 0 0 1 0.
Row 4. Decimal: 3. Binary: 0 0 1 1.
Row 5. Decimal: 4. Binary: 0 1 0 0.
Row 6. Decimal: 5. Binary: 0 1 0 1.
Row 7. Decimal: 6. Binary: 0 1 1 0.
Row 8. Decimal: 7. Binary: 0 1 1 1.
Row 9. Decimal: 8. Binary: 1 0 0 0.

Back to Table

The column entries from left to right are as follows.
Column 1. 2 to the power of 14: 16,384.
Column 2. 2 to the power of 13: 8,192.
Column 3. 2 to the power of 12: 4,096.
Column 4. 2 to the power of 11: 2,048.
Column 5. 2 to the power of 10: 1,024.
Column 6. 2 to the power of 9: 512.
Column 7. 2 to the power of 8: 256.
Column 8. 2 to the power of 7: 128.
Column 9. 2 to the power of 6: 64.
Column 10. 2 to the power of 5: 32.

Column 11. 2 to the power of 4: 16.
Column 12. 2 to the power of 3: 8.
Column 13. 2 to the power of 2: 4.
Column 14. 2 to the power of 1: 2.
Column 15. 2 to the power of 0: 1.

Back to Table

The equation reads: 11010, equals, 1 times 2 to the power of 4, plus, 1 times 2 to the power of 3, plus, 0 times 2 to the power of 2, plus, 1 times 2 to the power of 1, plus, 0 times 2 to the power of 0. This equals 16, plus, 8, plus, 0, plus, 2, plus 0 and this evaluates to 26.

The equation reads: 359, equals, 2 to the power of 8 times 1, plus, 2 to the power of 7 times 0, plus, 2 to the power of 6 times 1, plus, 2 to the power of 5 times 1, plus, 2 to the power of 4 times 0, plus, 2 to the power of 3 times 0, plus, 2 to the power of 2 times 1, plus, 2 to the power of 1 times 1, plus, 2 to the power of 0 times 1.

Back to Code

The equation reads: 359, equals, 2 to the power of 8 times 1, plus, 2 to the power of 7 times 0, plus, 2 to the power of 6 times 1, plus, 2 to the power of 5 times 1, plus, 2 to the power of 4 times 0, plus, 2 to the power of 3 times 0, plus, 2 to the power of 2 times 1, plus, 2 to the power of 1 times 1, plus, 2 to the power of 0 times 1. This equals 1 0 1 1 0 0 1 1 1.

Back to Code

The table has 2 columns labelled Hex Digit and Binary Value. The row entries are as follows.
Row 1. Hex Digit: 0. Binary Value: 0 0 0 0.
Row 2. Hex Digit: 1. Binary Value: 0 0 0 1.
Row 3. Hex Digit: 2. Binary Value: 0 0 1 0.
Row 4. Hex Digit: 3. Binary Value: 0 0 1 1.
Row 5. Hex Digit: 4. Binary Value: 0 1 0 0.
Row 6. Hex Digit: 5. Binary Value: 0 1 0 1.
Row 7. Hex Digit: 6. Binary Value: 0 1 1 0.
Row 8. Hex Digit: 7. Binary Value: 0 1 1 1.
Row 9. Hex Digit: 8. Binary Value: 1 0 0 0.
Row 10. Hex Digit: 9. Binary Value: 1 0 0 1.
Row 11. Hex Digit: A. Binary Value: 1 0 1 0.
Row 12. Hex Digit: B. Binary Value: 1 0 1 1.
Row 13. Hex Digit: C. Binary Value: 1 1 0 0.
Row 14. Hex Digit: D. Binary Value: 1 1 0 1.
Row 15. Hex Digit: E. Binary Value: 1 1 1 0.
Row 16. Hex Digit: F. Binary Value: 1 1 1 1.

Back to Table

The bits of the binary number are grouped in sets of 4. The binary number from the most significant to the least significant bit is as follows: 0 0 0 1, blank space, 1 0 1 0, blank space, 1 1 1 1, blank space, 1 0 0 1, blank space, 1 0 1 1, blank space, 0 0 1 1, blank space, 1 0 1 1, blank space, 1 1 1 0. The hexadecimal equivalent of the binary number is as follows: 1 A F 9 B 3 B E.

Back to Code

The bits of the binary number are grouped in sets of 4. The binary number from the most significant to the least significant bit is as follows: 1 1 0 0, blank space, 1 0 1 0, blank space, 1 1 1 1, blank space, 1 1 1 0, blank space, 1 0 1 1, blank space, 1 0 1 0, blank space, 1 0 1 1, blank space, 1 1 1 0.

Back to Code

The hexadecimal number is grouped in sets of 4 hex digits. The digits are as follows: C A F E, blank space, B A B E.

Back to Code

The table has 3 columns labelled Unicode Character, Decimal Value, and Hex Value. The row entries are as follows.
Row 1. Unicode Character: N U L, the null character, left parentheses, a nonprintable character, right parentheses. Decimal Value: 0. Hex Value: 0 0 0 0.
Row 2. Unicode Character: asterisk. Decimal Value: 42. Hex Value: 0 0 2 A.

Row 3. Unicode Character: 1. Decimal Value: 49. Hex Value: 0 0 3 1.

Row 4. Unicode Character: 2. Decimal Value: 50. Hex Value: 0 0 3 2.

Row 5. Unicode Character: uppercase a. Decimal Value: 65. Hex Value: 0 0 4 1.

Row 6. Unicode Character: uppercase b. Decimal Value: 66. Hex Value: 0 0 4 2.

Row 7. Unicode Character: lowercase a. Decimal Value: 97. Hex Value: 0 0 6 1.

Row 8. Unicode Character: lowercase b. Decimal Value: 98. Hex Value: 0 0 6 2.

Row 9. Unicode Character: right brace. Decimal Value: 125. Hex Value: 0 0 7 D.

Row 10. Unicode Character: delete, left parentheses, a nonprintable character, right parentheses. Decimal Value: 127. Hex Value: 0 0 7 F.

Back to Table

Line 1: read first number. Line 2: read second number. Line 3: set total to, left parentheses, first number plus second number, right parentheses. Line 4: output total.

Back to Example

Line 1: read a number. Line 2: call the square root method, passing the number and receiving the square root. Line 3: output the square root of the number.

Back to Example

Line 1: read a number. Line 2: if the number is greater than or equal to 0. Line 3, indented once: write, double quotes, Number is positive, period, double quotes. Line 4: else. Line 5, indented once: write, double quotes, Number is negative, period, double quotes.

Back to Example

Line 1: set total to 0. Line 2: read a number. Line 3: while there was a number to read, repeat next two instructions. Line 4, indented once: add number to total. Line 5, indented once: read the next number. Line 6: write total.

Back to Example

java c Class Name, dot, java.

Back to Code

java Class Name.

Back to Code

java Class Name dot java.

Back to Code

java c, hyphen, version.

Back to Code

java c 17 point 0 point 1.

Back to Code

java, hyphen, version.

Back to Code

Line 1: java version, double quotes, 17 point 0 point 1, double quotes, 2021, hyphen, 10, hyphen, 19, L T S. Line 2: Java, left parentheses, T M, right parentheses, S E, Runtime Environment, left parentheses, build 17 point 0 point 1, plus, 12, hyphen, L T S, hyphen, 39, right parentheses. Line 3: Java Hot Spot, left parentheses, T M, right parentheses, 64, hyphen, Bit Server, V M, left parentheses, build 17 point 0 point 1, plus, 12, hyphen, L T S, hyphen, 39, comma, mixed mode, comma, sharing, right parentheses.

Back to Code

Program code. The words in the class name are merged. The code contains the keywords: public, class, static, void, main, String. Line 1: 2 forward slashes, First program in Java. Line 2: 2 forward slashes, Anderson, comma, Franceschi. Line 3: blank. Line 4: public class First Program. Line 5: left brace. Line 6, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 7, indented once: left brace. Line 8, indented twice: System dot out dot print l n, left parentheses, double quotes, Programming is not a spectator sport, exclamation mark, double quotes, right parentheses, semicolon. Line 9: blank. Line 10, indented twice: System dot exit, left parentheses, 0, right parentheses, semicolon. Line 11, indented once: right brace. Line 12: right brace.

Back to Example

Line 1: First Program dot java, colon, 8, colon, error, colon, cannot find symbol.
Line 2, indented twice: System dot out dot Print l n, left parentheses, double quotes, Programming is not a spectator sport, exclamation mark, double quotes, right parentheses, semicolon.
Line 3: a caret sign under the uppercase P of Print l n in Line 2.
Line 4, indented once: symbol, colon, method Print l n, left parentheses, String, right parentheses.
Line 5, indented once: location, colon, variable out of type Print Stream.
Line 6: 1 error.

Back to Code

Line 1: First Program dot java, colon, 6, colon, error, colon, single quote, semicolon, single quote, expected.
Line 2, indented twice: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses.
Line 3: a caret sign below the right parentheses of Line 2.
Line 4: blank.

Line 5: First Program dot java, colon, 10, colon, error, colon, left angled bracket, identifier, right angled bracket, expected.
Line 6, indented twice: System dot exit, left parentheses, 0, right parentheses, semicolon.
Line 7: a caret sign below the left parentheses of Line 6.
Line 8: blank.
Line 9: First Program dot java, colon, 10, colon, error, colon, illegal start of type.
Line 10, indented twice: System dot exit, left parentheses, 0, right parentheses, semicolon.
Line 11: a caret sign below 0 in Line 10.
Line 12: blank.
Line 13: First Program dot java, colon, 12, colon, error, colon, class, comma, interface or enum expected.
Line 14: right brace.
Line 15: a caret sign under the right brace of Line 14.
Line 16: 4 errors.

Back to Code

Line 1: Error, colon, Main method not found in class First Program, comma, please define the main method as, colon.
Line 2, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses.
Line 3: or a Java F X application class must extend java f x dot application dot Application.

Back to Code

The table has 2 columns labelled Type of Error, and Usual Causes. The row entries are as follows.
Row 1. Type of Error: Compiler errors. Usual Causes: Incorrect language syntax or misspellings.
Row 2. Type of Error: Run time errors. Usual Causes: Incorrect use of classes.
Row 3. Type of Error: Logic errors. Usual Causes: Incorrect program design or incorrect implementation of the design.

Back to Table

Dot back slash jar c f, single quote, C, colon, back slash, Users, back slash, h e r v e, back slash, Documents, back slash, My Jar dot jar, single quote, First Program dot class.

Back to Code

Dot back slash jar, hyphen, hyphen, create, blank space, hyphen, hyphen, file, single quote, C, colon, back slash, Users, back slash, h e r v e, back slash, Documents, back slash, My Jar dot jar, single quote, dot, back slash, First Program dot class.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, String. Line 1: Forward slash, asterisk, An application shell. Line 2, indented once: Anderson, Franceschi. Line 3: asterisk, forward slash. Line 4: public class Shell Application. Line 5: left brace. Line 6, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. 2 forward slashes, required. Line 7, indented once: left brace. Line 8, indented twice: 2 forward slashes, write your code here. Line 9, indented once: right brace. Line 10: right brace.

Back to Example

The title of the table is Java Identifiers. The table entries are as follows. Must start with a Java letter, left parentheses, uppercase a, hyphen, uppercase z, lowercase a, hyphen, lowercase z, underscore, dollar sign, or many Unicode characters, right parentheses. Can contain an almost unlimited number of letters and, or, digits, left parentheses, 0 hyphen 9, right parentheses. Cannot contain spaces. Are case sensitive. Cannot be a Java reserved word.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, String, final, double. Line 1: forward slash, asterisk, Calculate the area of a circle. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Area Of Circle. Line 6: left brace. Line 7, indented once:

public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: 2 forward slashes, define the data we know. Line 10, indented twice: final double PI, equals, 3.14159, semicolon. Line 11: blank. Line 12, indented twice: 2 forward slashes, define other data we will use. Line 13, indented twice: double radius, equals, 3.5, semicolon. Line 14: blank. Line 15, indented twice: 2 forward slashes, perform the calculation and store the result. Line 16, indented twice: double area, equals, PI, asterisk, radius, asterisk, radius, semicolon. Line 17: blank. Line 18, indented twice: 2 forward slashes. Output the result. Line 19, indented twice: System dot out dot print l n, left parentheses, double quotes, The area of the circle is, double quotes, plus, area, right parentheses, semicolon. Line 20, indented once: right brace. Line 21: right brace.

Back to Example

The syntax is as follows. data Type identifier, semicolon. 2 forward slashes. This declares one variable.

Back to Code

The syntax is as follows. Line 1: data Type identifier 1, comma, identifier 2, comma, dot, dot, dot, semicolon. 2 forward slashes. This declares multiple. Line 2, indented multiple times: 2 forward slashes. Variables of the same.

Line 3, indented multiple times: 2 forward slashes. Data type.a

Back to Code

The table has 4 columns labelled Integer data type, Size in Bytes, Minimum value, and Maximum value. The row entries are as follows.
Row 1. Integer data type: byte. Size in Bytes: 1. Minimum Value: negative 128. Maximum value: 127.
Row 2. Integer data type: short. Size in Bytes: 2. Minimum Value: negative 32,768. Maximum value: 32,767.
Row 3. Integer data type: int. Size in Bytes: 4. Minimum Value: negative 2,147,483,648. Maximum value: 2,147,483,647.
Row 4. Integer data type: long. Size in Bytes: 8. Minimum Value: negative 9,223,372,036,854,775,808. Maximum value: 9,223,372,036,854,775,807.

Back to Table

The declarations are as follows.
Line 1: int test Grade, semicolon.
Line 2: int num Players, comma, high Score, comma, dice Roll, semicolon.
Line 3: short x Coordinate, comma, y Coordinate, semicolon.
Line 4: long city Population, semicolon.
Line 5: byte age In Years, semicolon.

Back to Code

The table has 4 columns labelled Floating point data type, Size in bytes, Minimum Positive Nonzero value, and Maximum value. The row entries are as follows.
Row 1. Floating Point Data Type: float. Size in Bytes: 4. Minimum Positive Nonzero Value: 1.4 E negative 45. Maximum Value: 3.4028235 E 38.
Row 2. Floating Point Data Type: double. Size in Bytes: 8. Minimum Positive Nonzero Value: 4.9 E negative 324. Maximum Value: 1.7976931348623157 E 308.

Back to Table

The declarations are as follows.
Line 1: float sales Tax, semicolon.
Line 2: double interest Rate, semicolon.
Line 3: double paycheck, comma, sum Salaries, semicolon.

Back to Code

The table has 4 columns labelled Character Data Type, Size in Bytes, Minimum Value, and Maximum value. The row entries are as follows.
Row 1. Character data type: char. Size in Bytes: 2. Minimum Value: The character encoded as 0 0 0 0, the null character. Maximum Value: The value F F F F, which is a special code for, double quotes, not a character, double quotes.

Back to Table

The declarations are as follows.
Line 1: char final Grade, semicolon.
Line 2: char middle Initial, semicolon.
Line 3: char new line, comma, tab, comma, double Quotes, semicolon.

Back to Code

The table has 2 columns labelled Boolean Data Type and Possible Values. The row entries are as follows.
Row 1. Boolean Data Type: Boolean. Possible Values: true.
Row 2. Boolean Data Type: blank. Possible Values: false.

Back to Table

The declarations are as follows.
Line 1: boolean is Empty, semicolon.
Line 2: Boolean passed, comma, failed, semicolon.

Back to Code

The syntax is as follows. data Type variable Name equals initial Value, semicolon.

Back to Code

The syntax is as follows. data Type variable 1 equals initial Value 1, comma, variable 2 equals initial Value 2, semicolon.

Back to Code

The statement is as follows. Line 1: int test Grade equals 100, semicolon.

Back to Code

The table has 2 columns labelled Data Type and Literal Format. The row entries are as follows.
Row 1. Data Type: int, short, byte. Literal Format: Optional initial sign, left parentheses, plus or minus, right parentheses, followed by digits 0 hyphen 9 in any combination. A literal in this format is an int literal, semicolon, however, an int literal may be assigned to a byte or short variable if the literal is a legal value for the assigned data type. An integer literal that begins with a 0 digit is considered to be an octal number, left parentheses, base 8, right parentheses, and the remaining digits must be 0 hyphen 7. An integer literal that begins with 0 x is considered to be an hexadecimal number, left parentheses, base 16, right parentheses, and the remaining digits must be 0 hyphen 9 or A hyphen F.
Row 2. Data Type: long. Literal Format: Optional initial sign, left parentheses, plus or minus, right parentheses, followed by digits 0 hyphen 9 in any combination, terminated with an uppercase l or lowercase l. It’s preferable to use the capital l, because the lowercase l can be confused with the number 1. An integer literal that begins with a 0 digit is considered to be an octal number, left parentheses, base 8, right parentheses, and the remaining digits must be 0 hyphen 7. An integer literal that begins with 0 x is considered to be a hexadecimal

number, left parentheses, base 16, right parentheses, and the remaining digits must be 0 hyphen 9 or A hyphen F. Row 3. Data Type: float. Literal Format: Optional initial sign, left parentheses, plus or minus, right parentheses, followed by a floating point number in fixed or scientific format, terminated by an upper case f or lowercase f. Row 4. Data Type: double. Literal Format: Optional initial sign, left parentheses, plus or minus, right parentheses, followed by a floating point number in fixed or scientific format. Row 5. Data Type: char. Literal Format: Any printable character enclosed in single quotes. A decimal value from 0 to 65,535. Single quote, back slash, u n n n n, single quote, where n n n n are hexadecimal digits. Single quote, back slash m, single quote, where back slash m is an escape sequence. For example, single quote, back slash n, single quote, represents a newline and single quote, back slash, t, single quote, represents a tab character. Row 6. Data Type: boolean. Literal Format: true or false.

Back to Table

Line 1: j shell, right angled bracket, int test Grade, equals, 100, semicolon. Line 2: test Grade, equals, equals, right angled bracket, 100. Line 3: j shell, right angled bracket, long city Population, equals, 425612340, uppercase l, semicolon. Line 4: city Population, equals, equals, right angled bracket, 425612340. Line 5: j shell, right angled bracket, byte number Of Pets, equals, 2, semicolon. Line 6: number Of Pets, equals, equals, right angled bracket,

2. Line 7: j shell, right angled bracket, short age In Years, equals, 19, semicolon. Line 8: age In Years, equals, equals, right angled bracket, 19. Line 9: j shell, right angled bracket, float sales Tax, equals, decimal point, 0 5, uppercase f, semicolon. Line 10: sales Tax, equals, equals, right angled bracket, 0.05. Line 11: j shell, right angled bracket, double interest Rate, equals, 0.0425, semicolon. Line 12: interest Rate, equals, equals, right angled bracket, 0.0425. Line 13: j shell, right angled bracket, double avogadro Number, equals, plus, 6.022, uppercase e, 23, semicolon. Line 14: avogadro Number, equals, equals, right angled bracket, 6.022, uppercase e, 23. Line 15: j shell, right angled bracket, char final Grade, equals, single quote, uppercase a, single quote, semicolon. Line 16: final Grade, equals, equals, right angled bracket, single quote, uppercase a, single quote. Line 17: j shell, right angled bracket, boolean is Empty, equals, true, semicolon. Line 18: is Empty, equals, equals, right angled bracket, true.

Back to Example

The syntax is as follows. data Type variable 2 equals variable 1, semicolon.

Back to Code

Line 1: j shell, right angled bracket, forward slash, v a r s. Line 2: pipe, blank spaces, int test Grade equals 100. Line 3: pipe, blank spaces, long city Population equals

425612340.
Line 4: pipe, blank spaces, byte number Of Pets equals 2.
Line 5: pipe, blank spaces, short age In Years equals 19.
Line 6: pipe, blank spaces, float sales Tax equals 0.05.
Line 7: pipe, blank spaces, double interest Rate equals 0.0425.
Line 8: pipe, blank spaces, double Avogadro Number equals 6.022 E 23.
Line 9: pipe, blank spaces, char final Grade equals, single quote, uppercase a, single quote.
Line 10: pipe, blank spaces, boolean Is Empty equals true.
Line 11: j shell, right angled bracket.

Back to Code

Line 1: j shell, right angled bracket, boolean Is Passing Grade equals true, semicolon.
Line 2: is Passing Grade, 2 equals sign, right angled bracket, true.
Line 3: blank.
Line 4: j shell, right angled bracket, boolean Is Promoted equals is Passing Grade, semicolon.
Line 5: is Promoted, 2 equals sign, right angled bracket, true.

Back to Code

Line 1: j shell, right angled bracket, float sales Tax equals .05 f, semicolon.

Line 2: sales Tax, 2 equals sign, right angled bracket, 0.05.
Line 3: blank.
Line 4: j shell, right angled bracket, double tax Rate equals sales Tax, semicolon.
Line 5: tax Rate, 2 equals sign, right angled bracket, 0.05000000074505806.

Back to Code

The table has 2 columns labelled Data Type and Compatible Data Types. The row entries are as follows.
Row 1. Data Type: byte. Compatible Data Types: byte.
Row 2. Data Type: short. Compatible Data Types: byte, short.
Row 3. Data Type: int. Compatible Data Types: byte, short, int, char.
Row 4. Data Type: long. Compatible Data Types: byte, short, int, char, long.
Row 5. Data Type: float. Compatible Data Types: byte, short, int, char, long, float.
Row 6. Data Type: double. Compatible Data Types: byte, short, int, char, long, float, double.
Row 7. Data Type: boolean. Compatible Data Types: boolean.
Row 8. Data Type: char. Compatible Data Types: char.

Back to Table

The statements are as follows.

Line 1: double two Cents, semicolon.
Line 2: double two Cents equals 2, semicolon. 2 forward slashes. Incorrect, second declaration of two Cents.

Back to Code

The statements are as follows.
Line 1: double cash In Hand, semicolon.
Line 2: int cash In Hand, semicolon. 2 forward slashes. Incorrect, data type cannot be changed.

Back to Code

Line 1: double quotes, Hello, double quotes.
Line 2: double quotes, Hello, blank space, world, double quotes.
Line 3: double quotes, The value of x is, blank space, double quotes.

Back to Code

The statement is as follows. Line 1: System dot out dot print l n, left parentheses, double quotes, Never pass a water fountain. Line 2, indented multiple times: without taking a drink, dot, double quotes, right parentheses, semicolon.

Back to Code

Line 1: j shell, right angled bracket, blank space, System dot out dot print l n, left parentheses, double quotes, Never pass a water fountain.

Line 2: pipe, blank space, Error, colon.
Line 3: pipe, blank space, unclosed string literal.
Line 4: pipe, blank space, System dot out dot print l n, Never pass a water fountain.
Line 5: pipe followed by multiple indents. A caret symbol is printed below the double quotes in Line 4.

Back to Code

Line 1: j shell, right angled bracket, blank space, System dot out dot print l n, left parentheses, double quotes, Never pass a water fountain, double quotes.
Line 2: dot, dot, dot, right angled bracket. Multiple indents. Plus, double quotes, without taking a drink, dot, double quotes, right parentheses, semicolon.
Line 3: Never pass a water fountain without taking a drink, dot.

Back to Code

Line 1: System dot out dot print l n, left parentheses, double quotes, She said, comma, double quotes, Java is fun, double quotes, dot, double quotes, right parentheses, semicolon. 2 forward slashes. Illegal quotes.
Line 2, indented multiple times: 2 forward slashes. Within literal.

Back to Code

Line 1: j shell, right angled bracket, blank space, System dot out dot print l n, left parentheses, double quotes, She

said, comma, double quotes, Java is fun, double quotes, dot, double quotes, right parentheses, semicolon.
Line 2: pipe, blank space, Error, colon.
Line 3: pipe, single quote, right parentheses, single quote, expected.
Line 4: pipe, System dot out dot print l n, left parentheses, double quotes, She said, comma, double quotes, Java is fun, double quotes, dot, double quotes, right parentheses, semicolon.
Line 5: pipe, multiple indents. Caret sign under the uppercase j character in line 4.

Back to Code

The table has 2 columns labelled Character and Escape Sequence. The row entries are as follows.
Row 1. Character: newline. Escape Sequence: backslash n.
Row 2. Character: tab. Escape Sequence: backslash t.
Row 3. Character: double quotes. Escape Sequence: backslash, double quotes.
Row 4. Character: single quote. Escape Sequence: backslash, single quote.
Row 5. Character: backslash. Escape Sequence: 2 backslashes.
Row 6. Character: backspace. Escape Sequence: backslash b.
Row 7. Character: carriage return. Escape Sequence: backslash r.
Row 8. Character: form feed. Escape Sequence:

backslash f.

Back to Table

Line 1: j shell, right angled bracket, blank space, System dot out dot print l n, left parentheses, double quotes, She said, comma, back slash, double quotes, Java is fun, back slash, double quotes, dot, double quotes, right parentheses, semicolon.
Line 2: She said, comma, double quotes, Java is fun, double quotes, dot.

Back to Code

Line 1: j shell, right angled bracket, System dot out dot print l n, left parentheses, double quotes, One potato, back slash, n, Two potatoes, double quotes, right parentheses, semicolon.
Line 2: One potato Two potatoes.

Back to Code

Line 1: j shell, right angled bracket, System dot out dot print l n, left parentheses, double quotes, backslash, t, Tabs can make the output easier to read, dot, double quotes, right parentheses, semicolon.
Line 2, indented once: Tabs can make the output easier to read, dot.

Back to Code

Program code. The code contains the following keywords:

public, class, static, void, String. Line 1: forward slash, asterisk, Using Text Blocks. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Text Block. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: String menu, equals, 3 double quotes. Line 10, indented thrice: Please choose a language, colon. Line 11, indented thrice: back slash, t 1, hyphen, Java. Line 12, indented thrice: back slash, t 2, hyphen, Python. Line 13, indented thrice: back slash, t 3, hyphen, C, plus, plus. Line 14, indented thrice: 3 double quotes, semicolon. Line 15: blank. Line 16, indented twice: System dot out dot print l n, left parentheses, menu, right parentheses, semicolon. Line 17, indented once: right brace. Line 18: right brace.

Back to Example

Program code. The code contains the following keywords: public, class, static, void, final, char, double, int. Line 1: forward slash, asterisk, Constants Class. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Constants. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: final char ZORRO, equals, single quote, uppercase z, single quote, semicolon. Line 10, indented twice: final double PI, equals, 3.14159, semicolon. Line 11, indented twice: final int DAYS underscore IN underscore LEAP underscore YEAR, equals, 366, comma, DAYS underscore IN underscore NON underscore LEAP underscore YEAR, equals, 365, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of constant ZORRO is, double quotes, plus, ZORRO, right parentheses, semicolon. Line 14, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of constant PI is, double quotes, plus, PI, right parentheses, semicolon. Line 15, indented twice: System dot out dot print l n, left parentheses, double quotes, The number of days in a leap year is, double quotes. Line 16, indented multiple times: plus, DAYS underscore IN underscore LEAP underscore YEAR, right parentheses, semicolon. Line 17, indented twice: System dot out dot print l n, left parentheses, double quotes, The number of days in a non, hyphen, leap year is, double quotes. Line 18, indented multiple times: plus, DAYS underscore IN underscore NON underscore LEAP underscore YEAR, right parentheses, semicolon. Line 19: blank. Line 20, indented twice: 2 forward slashes, PI, equals, 3.14, semicolon. Line 21, indented twice: 2 forward slashes, The statement above would generate a compiler error. Line 22, indented twice: 2 forward slashes, You cannot change the value of a constant. Line 23, indented once: right brace. Line 24: right brace.

Back to Example

The syntax is as follows. target equals expression, semicolon.

Back to Code

Line 1: j shell, right angled bracket, int number Of Players equals 10, semicolon.
Line 2: number Of Players, 2 equals sign, right angled bracket, 10.
Line 3: j shell, right angled bracket, number Of Players equals 8, semicolon.
Line 4: number Of Players, 2 equals sign, right angled bracket, 8.
Line 5: j shell, right angled bracket, forward slash, vars.
Line 6: pipe, single indent, int number Of Players, equals, 8.

Back to Code

Line 1: j shell, right angled bracket, int legal Age equals 18, semicolon.
Line 2: legal Age, 2 equals sign, right angled bracket, 18.
Line 3: j shell, right angled bracket, int voter Age equals legal Age, semicolon.
Line 4: voter Age, 2 equals sign, right angled bracket, 18.

Back to Code

The declarations are as follows.

Line 1: int length equals width asterisk 2, semicolon. 2 forward slashes. Invalid, comma, width is not yet defined.
Line 2: int width equals 30, semicolon.

Back to Code

Line 1: j shell, right angled bracket, int length equals width asterisk 2, semicolon.
Line 2: pipe, blank space, Error, colon.
Line 3: pipe, blank space, cannot find symbol.
Line 4: pipe, tab space, symbol, colon, variable width.
Line 5: pipe, blank space, int length equals width asterisk 2, semicolon.
Line 6: pipe, multiple indents, caret sign below lowercase w in line 5.

Back to Code

Row 1. Operator: plus sign. Operation: addition.
Row 2. Operator: minus sign. Operation: subtraction.
Row 3. Operator: asterisk. Operation: multiplication.
Row 4. Operator: forward slash. Operation: division.
Row 5. Operator: percentage sign. Operation: modulus, left square bracket, remainder after division, right square bracket.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, double, String, int. Line 1: forward slash, asterisk, Arithmetic Operators. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Arithmetic Operators. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: 2 forward slashes, calculate the cost of lunch. Line 10, indented twice: double salad, equals, 5.95, semicolon. Line 11, indented twice: double water, equals, decimal point, 89, semicolon. Line 12, indented twice: System dot out dot print l n, left parentheses, double quotes, The cost of lunch is, dollar sign, double quotes. Line 13, indented multiple times: plus, left parentheses, salad, plus, water, right parentheses, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: 2 forward slashes, calculate your age as of a certain year. Line 16, indented twice: int target Year, equals, 2025, semicolon. Line 17, indented twice: int birth Year, equals, 2005, semicolon. Line 18, indented twice: System dot out dot print l n, left parentheses, double quotes, Your age in, double quotes, plus, target Year, plus, double quotes, is, double quotes. Line 19, indented multiple times: plus, left parentheses, target Year, minus, birth Year, right parentheses, right parentheses, semicolon. Line 20: blank. Line 21, indented twice: 2 forward slashes, calculate the total calories of apples. Line 22, indented twice: int calories Per Apple, equals, 127, semicolon. Line 23, indented twice: int number Of Apples, equals, 3, semicolon. Line 24, indented twice: System dot out dot print l n, left parentheses, double quotes, The calories in, double quotes, plus, number Of Apples. Line 25, indented multiple times: plus, double quotes, apples is, double quotes, plus. Line 26, indented multiple times: plus, left parentheses, calories Per Apple, asterisk, number Of Apples, right parentheses, right parentheses, semicolon. Line 27: blank. Line 28, indented twice: 2 forward slashes, calculate miles per gallon. Line 29, indented twice: double miles, equals, 426.8, semicolon. Line 30, indented twice: double gallons, equals, 15.2, semicolon. Line 31, indented twice: double mileage, equals, miles, forward slash, gallons, semicolon. Line 32, indented twice: System dot out dot print l n, left parentheses, double quotes, The mileage is, double quotes. Line 33, indented multiple times: plus, mileage, plus, double quotes, miles per gallon, period, double quotes, right parentheses, semicolon. Line 34, indented once: right brace. Line 35: right brace.

Back to Example

Line 1: equals, 2 asterisk, 25, plus, 3, asterisk, 10, plus, 2, asterisk, 5.
Line 2: equals, blank space, 50, blank space, plus, 3, asterisk, 10, plus, 2, asterisk, 5.
Line 3: equals, blank spaces, 53, blank spaces, asterisk, 10, plus, 2, asterisk, 5.
Line 4: equals, blank spaces, 530, blank spaces, plus, 2, asterisk, 5.
Line 5: equals, blank spaces, 532, asterisk, 5.

Line 6: equals, blank spaces, 2660.

Back to Code

The table has 3 columns labelled Operator Hierarchy, Order of Same Statement Evaluation, and Operation. The row entries are as follows.
Row 1. Operator Hierarchy: left parentheses, right parentheses. Order of Same Statement Evaluation: left to right. Operation: parentheses for explicit grouping.
Row 2. Operator Hierarchy: asterisk, forward slash, percentage sign. Order of Same Statement Evaluation: left to right. Operation: multiplication, division, modulus.
Row 3. Operator Hierarchy: plus, minus. Order of Same Statement Evaluation: left to right. Operation: addition, subtraction.
Row 4. Operator Hierarchy: equals sign. Order of Same Statement Evaluation: right to left. Operation: assignment.

Back to Table

Line 1: int pennies equals 2 asterisk 25 plus 3 asterisk 10 plus 2 asterisk 5, semicolon.
Line 2, indented twice: equals, 50 plus 30 plus 10.
Line 3, indented twice: equals, 90.

Back to Code

Line 1: int pennies equals, left parentheses, 2 asterisk 25, right parentheses, plus, left parentheses, 3 asterisk 10, right parentheses, plus, left parentheses, 2 asterisk 5,

right parentheses, semicolon.
Line 2, indented once: equals, 50, plus, 30, plus, 10.
Line 3, indented once: equals 90.

Back to Code

Line 1: j shell, right angled bracket, int pennies equals 2 asterisk 25 plus 3 asterisk 10 plus 2 asterisk 5, semicolon.
Line 2: pennies, 2 equals sign, right angled bracket, 90.
Line 3: j shell, right angled bracket, pennies, equals, left parentheses, 2 asterisk 25, right parentheses, plus, left parentheses, 3 asterisk 10, right parentheses, plus, left parentheses, 2 asterisk 5, right parentheses, semicolon.
Line 4: pennies, 2 equals sign, right angled bracket, 90.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, String. Line 1: Forward slash, asterisk. Metric Length, hyphen, converts inches to centimeters. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Metric Length. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9: blank. Line 10, indented twice: Forward slash, 5 asterisks, 1, period, What data values do we know, question mark. Line 11, indented thrice: We know that there are 2.54 centimeters in an inch. Line 12, indented thrice: Declare a double constant named C M underscore PER underscore INCH. Line 13, indented thrice: Assign C M underscore PER underscore INCH the value 2.54. Line 14, indented twice: asterisk, forward slash. Line 15: blank. Line 16: blank. Line 17, indented twice: forward slash, 5 asterisks, 2. What other data does the program require, question mark. Line 18, indented thrice: For this program, comma, we require the number of inches. Line 19, indented thrice: Declare a double variable named inches. Line 20, indented thrice: Assign any desired value to this variable. Line 21, indented twice: asterisk, forward slash. Line 22: blank. Line 23: blank. Line 24, indented twice: Forward slash, 5 asterisks, 3. Calculation, colon, convert inches to centimeters. Line 25, indented thrice: Declare a double variable named centimeters. Line 26, indented thrice: Multiply inches by C M underscore PER underscore INCH. Line 27, indented thrice: and store the result in centimeters. Line 28, indented twice: asterisk, forward slash. Line 29: blank. Line 30: blank. Line 31, indented twice: Forward slash, 5 asterisks. 4. Output. Line 32, indented thrice: Write one or two statements that output. Line 33, indented thrice: the original inches and the equivalent centimeters. Line 34, indented thrice: Try to match the sample output in Figure 2.5. Line 35, indented twice: asterisk, forward slash. Line 36: blank. Line 37: blank. Line 38: blank. Line 39, indented once: right brace. Line 40: right brace.

Back to Example

Program code. The code contains the following keywords: public, class, static, void, String, final, int, double. Line 1: Forward slash, asterisk. Division And Modulus Class. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: public class Division And Modulus. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: final int PENNIES underscore PER underscore QUARTER, equals 25, semicolon. Line 10, indented twice: int pennies, equals, 113, semicolon. Line 11: blank. Line 12, indented twice: int quarters, equals, pennies, forward slash, PENNIES underscore PER underscore QUARTER, semicolon. Line 13, indented twice: System dot out dot print l n, left parentheses, double quotes, There are, double quotes, plus, quarters, plus, double quotes, blank space, quarters in, blank space, double quotes. Line 14, indented multiple times: plus, pennies, plus, double quotes, blank space, pennies, double quotes, right parentheses, semicolon. Line 15: blank. Line 16, indented twice: int pennies Left Over, equals, pennies, percentage sign, PENNIES underscore PER underscore QUARTER, semicolon. Line 17, indented twice: System dot out dot print l n, left parentheses, double quotes, There are, blank space, double quotes, plus, pennies Left Over. Line 18, indented multiple times: plus, double quotes, blank space, pennies left over, double quotes, right parentheses, semicolon.

Line 19: blank. Line 20, indented twice: final double MONTHS underscore PER underscore YEAR, equals, 12, semicolon. Line 21, indented twice: double annual Salary, equals, 50000.0, semicolon. Line 22: blank. Line 23, indented twice: double monthly Salary, equals, annual Salary, forward slash, MONTHS underscore PER underscore YEAR, semicolon. Line 24, indented twice: System dot out dot print l n, left parentheses, double quotes, The monthly salary is, double quotes, plus, monthly Salary, right parentheses, semicolon. Line 25, indented once: right brace. Line 26: right brace.

Back to Example

Program code. The code contains the following keywords: public, class, static, void, String, double, int. Line 1: Forward slash, asterisk. Division by Zero Class. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: public class Division By Zero. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: double result, equals, 4.3, forward slash, 0.0, semicolon. Line 10, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of result 1 is, blank space, double quotes, plus, result 1, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: double result 2, equals, 0.0, forward slash, 0.0, semicolon. Line 13, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of result 2 is, double quotes, plus, result 2, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: int result 3, equals, 4, forward slash, 0, semicolon. Line 16, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of result 3 is, double quotes, plus, result 3, right parentheses, semicolon. Line 17, indented once: right brace. Line 18: right brace.

Back to Example

The table has 4 columns labelled Data Type of One Operand, Data Type of Other Operand, Promotion of Other Operand, and Data Type of Result. The row entries are as follows.
Row 1. Data Type of One Operand: double. Data Type of Other Operand: char, byte, short, int, long, float. Promotion of Other Operand: double. Data Type of Result: double.
Row 2. Data Type of One Operand: float. Data Type of Other Operand: char, byte, short, int, long. Promotion of Other Operand: float. Data Type of Result: float.
Row 3. Data Type of One Operand: long. Data Type of Other Operand: char, byte, short, int. Promotion of Other Operand: long. Data Type of Result: long.
Row 4. Data Type of One Operand: int. Data Type of Other Operand: char, byte, short. Promotion of Other Operand: int. Data Type of Result: int.
Row 5. Data Type of One Operand: short. Data Type of

Other Operand: char, byte. Promotion of Other Operand: Both operands are promoted to int. Data Type of Result: int.
Row 6. Data Type of One Operand: byte. Data Type of Other Operand: char. Promotion of Other Operand: Both operands are promoted to int. Data Type of Result: int.

Back to Table

Line 1: j shell, right angled bracket, int radius equals 4, semicolon.
Line 2: radius, 2 equals sign, right angled bracket, 4.
Line 3: j shell, right angled bracket, int radius Squared equals radius asterisk radius, semicolon.
Line 4: radius Squared, 2 equals sign, right angled bracket, 16.
Line 5: j shell, right angled bracket, double area equals 3.14159 asterisk radius Squared, semicolon.
Line 6: area, 2 equals sign, right angled bracket, 50.26544.
Line 7: j shell, right angled bracket, forward slash, vars.
Line 8: pipe, blank spaces, int radius equals 4.
Line 9: pipe, blank spaces, int radius Squared equals 16.
Line 10: pipe, blank spaces, double area equals 50.26544.

Back to Code

Line 1: j shell, right angled bracket, int total Scores equals 94 plus 86 plus 88 plus 97, semicolon.

Line 2: total Scores, 2 equals sign, right angled bracket, 365.
Line 3: blank.
Line 4: j shell, right angled bracket, int count equals 4, semicolon.
Line 5: count, 2 equals sign, right angled bracket, 4.
Line 6: blank.
Line 7: j shell, right angled bracket, total Scores, forward slash, count.
Line 8: dollar sign, 3, 2 equals sign, right angled bracket, 91.
Line 9: blank.
Line 10: j shell, right angled bracket, double average equals total Scores forward slash count, semicolon.
Line 11: average, 2 equals sign, right angled bracket, 91.0.

Back to Code

Line 1: j shell, right angled bracket, left parentheses, double, right parentheses, left parentheses, total Scores, forward slash, count, right parentheses.
Line 2: dollar sign, 7, 2 equals sign, right angled bracket, 91.0.
Line 3: blank.
Line 4: j shell, right angled bracket, average, equals, left parentheses, double, right parentheses, left parentheses, total Scores, forward slash, count, right parentheses, semicolon.
Line 5: average, 2 equals sign, right angled bracket, 91.0.

Back to Code

Line 1: j shell, right angled bracket, left parentheses, double, right parentheses, total Scores, forward slash, count.
Line 2: dollar sign, 9, 2 equals sign, right angled bracket, 91.25.
Line 3: blank.
Line 4: j shell, right angled bracket, average, equals, left parentheses, double, right parentheses, total Scores, forward slash, count, semicolon.
Line 5: average, 2 equals sign, right angled bracket, 91.25.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, String, int. Line 1: Forward slash, asterisk. Shortcut Operators Class. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: public class Shortcut Operators. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: int a, equals, 6, semicolon. Line 10, indented once: int b, equals, 2, semicolon. Line 11: blank. Line 12, indented once: System dot out dot print l n, left parentheses, double quotes, At the begining, comma, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 13, indented twice: System dot out dot print l n, left parentheses, double quotes, Increment a with prefix notation, colon, blank space, double quotes, plus, 2 plus symbols, a, right parentheses, semicolon. Line 14, indented twice: System dot out dot print l n, left parentheses, double quotes, In the end, comma, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 16, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, At the begining, comma, b is, blank space, double quotes, plus, b, right parentheses, semicolon. Line 17, indented twice: System dot out dot print l n, left parentheses, double quotes, Increment b with postfix notation, colon, blank space, double quotes, plus, b, plus, plus, right parentheses, semicolon. Line 18, indented twice: System dot out dot print l n, left parentheses, double quotes, In the end, comma, b is, blank space, double quotes, plus, b, right paentheses, semicolon. Line 19, indented once: right brace. Line 20: right brace.

Back to Example

The statements are as follows.
Line 1: int length equals 3, semicolon. 2 forward slashes. Length in feet.
Line 2: length asterisk equals 12, semicolon. 2 forward slashes. Length converted to inches.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, String, int. Line 1: Forward slash, asterisk. Shortcut Arithmetic Operators. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, Forward slash. Line 4: blank. Line 5: public class Shortcut Arithmetic Operators. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: int a, equals, 5, semicolon. Line 10, indented twice: System dot out dot print l n, left parentheses, double quotes, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: a, plus, equals, 10, semicolon. 2 forward slashes. a equals, a plus 10, semicolon. Line 13, indented twice: System dot out dot print l n, left parentheses, double quotes, After a, plus, equals, 10, semicolon, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: a, minus, equals, 3, semicolon. 2 forward slashes. a, equals, a minus 3, semicolon. Line 16, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, After a, minus, equals, 3, semicolon, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 17: blank. Line 18, indented twice: a, asterisk, equals, 2, semicolon. 2 forward slashes, a, equals, a asterisk 2, semicolon. Line 19, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash n, After a asterisk, equals, 2, semicolon, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 20: blank. Line 21, indented twice: a, forward slash, equals, 6, semicolon. 2 forward slashes. a, equals, a, forward slash, 6, semicolon. Line 22, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash n, After a, forward slash, equals, 6, semicolon, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 23: blank. Line 24, indented twice: a, percentage sign, equals, 3, semicolon. 2 forward slashes, a, equals, a, percentage sign, 3, semicolon. Line 25, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash n, After a, percentage sign, equals, 3, semicolon, a is, blank space, double quotes, plus, a, right parentheses, semicolon. Line 26, indented once: right brace. Line 27: right brace.

Back to Example

The table has 3 columns labelled Shortcut Operator, Example, and Equivalent Statement. The row entries are as follows.
Row 1. Shortcut Operator: plus plus. Example: a plus plus, semicolon, or, plus plus a, semicolon. Equivalent Statement: a equals a plus 1, semicolon.
Row 2. Shortcut Operator: minus minus. Example: a minus minus, semicolon, or, minus minus a, semicolon. Equivalent Statement: a equals a minus 1, semicolon.
Row 3. Shortcut Operator: plus equals. Example: a plus equals 3, semicolon. Equivalent Statement: a equals a

plus 3, semicolon.
Row 4. Shortcut Operator: minus equals. Example: a minus equals 10, semicolon. Equivalent Statement: a equals a minus 10, semicolon.
Row 5. Shortcut Operator: asterisk equals. Example: a asterisk equals 4, semicolon. Equivalent Statement: a equals a asterisk 4, semicolon.
Row 6. Shortcut Operator: forward slash equals. Example: a forward slash equals 7, semicolon. Equivalent Statement: a equals a forward slash 7, semicolon.
Row 7. Shortcut Operator: percentage equals. Example: a percentage equals 10, semicolon. Equivalent Statement: a equals a percentage 10, semicolon.

Back to Table

The table has 3 columns labelled Operator Hierarchy, Order of Same Statement Evaluation, and Operation. The row entries are as follows.
Row 1. Operator Hierarchy: left parentheses, right parentheses. Order of Same Statement Evaluation: left to right. Operation: parentheses for explicit grouping.
Row 2. Operator Hierarchy: plus plus, minus minus. Order of Same Statement Evaluation: right to left. Operation: shortcut post increment.
Row 3. Operator Hierarchy: plus plus minus minus. Order of Same Statement Evaluation: right to left. Operation: shortcut pre increment.
Row 4. Operator Hierarchy: asterisk, forward slash, percentage sign. Order of Same Statement Evaluation:

left to right. Operation: multiplication, division, modulus.
Row 5. Operator Hierarchy: plus, minus. Order of Same Statement Evaluation: left to right. Operation: addition or String concatenation, subtraction.
Row 6. Operator Hierarchy: equals, plus equals, minus equals, asterisk equals, forward slash equals, percentage equals. Order of Same Statement Evaluation: right to left. Operation: assignment operator and shortcut assignment operators.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, String. Line 1: Forward slash, asterisk. Temperature Conversion. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Temperature Conversion. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: 2 forward slashes. 5 asterisks. 1. declare any constants here. Line 10: blank. Line 11: blank. Line 12, indented twice: 2 forward slashes. 5 asterisks. 2. declare the temperature in Fahrenheit as an int. Line 13: blank. Line 14: blank. Line 15, indented twice: 2 forward slashes. 5 asterisks. 3. Calculate equivalent Celsius temperature. Line 16: blank. Line 17: blank. Line 18, indented twice: 2 forward slashes. 5 asterisks. 4. output the temperature in Celsius. Line 19: blank. Line 20: blank.

Line 21, indented twice: 2 forward slashes. 5 asterisks. 5. convert Celsius temperature back to Fahrenheit. Line 22: blank. Line 23: blank. Line 24, indented twice: 2 forward slashes. 5 asterisks. 6. output Fahrenheit temperature to check correctness. Line 25: blank. Line 26: blank. Line 27, indented once: right brace. Line 28: right brace.

Back to Example

The syntax is as follows. data Type variable 1 equals initial Value 1, semicolon.

Back to Code

The syntax is as follows. final data Type CONSTANT underscore IDENTIFIER equals initial Value, semicolon.

Back to Code

Line 1: double a equals 12.5, semicolon.
Line 2: System dot out dot print l n, left parentheses, a, right parentheses, semicolon.

Line 2: blank space, asterisk, blank space, asterisk, blank space.
Line 3: 2 blank spaces, asterisk, 2 blank spaces.
Line 4: blank space, asterisk, blank space, asterisk, blank space.
Line 5: asterisk, 3 blank spaces, asterisk.

Back to Code

The text magnified by the lens reads: Look It Up.

Back to Figure

2 types of constructors are shown in the table. 1. String, left parentheses, String s t r, right parentheses. Allocates a String object with the value of s t r, which can be a String object or a String literal. 2. String, left parentheses,

right parentheses. Allocates an empty String object.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, String. Line 1: Forward slash, asterisk. A Demonstration of Using Constructors. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: public class Constructors. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: String empty String, semicolon. Line 10, indented twice: empty String, equals, new String, left parentheses, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: String greeting, semicolon. Line 13, indented twice: greeting, equals, new String, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: String first Name, equals, new String, left parentheses, double quotes, Jane, double quotes, right parentheses, semicolon. Line 16, indented once: right brace. Line 17: right brace.

Back to Example

The syntax is as follows. object Reference equals new Class Name, left parentheses, argument list, right parentheses, semicolon.

Back to Code

The table has 2 columns labelled Return Value and Method name and argument list. The row entries are as follows.
Line 1. Return Value: int. Method name and argument list: length, left parentheses, right parentheses, returns the length of the String.
Line 2. Return Value: String. Method name and argument list: to Upper Case, left parentheses, right parentheses, returns a copy of the String with all letters in uppercase.
Line 3. Return Value: String. Method name and argument list: to Lower Case, left parentheses, right parentheses, returns a copy of the String with all letters in lowercase.
Line 4. Return Value: char. Method name and argument list: char At, left parentheses, int index, right parentheses, returns the character at the position specified by index.
Line 5. Return Value: int. Method name and argument list: index Of, left parentheses, String search String, right parentheses, returns the index of the beginning of the first occurrence of search String or negative 1 if search String is not found.
Line 6. Return Value: int. Method name and argument list: index Of, left parentheses, char search Char, right parentheses, index Of, left parentheses, char search Char, right parentheses, returns the index of the first occurrence of search Char in the String or negative 1 if search Char is not found.
Line 7. Return Value: String. Method name and argument

list: substring, left parentheses, int start Index, comma, int end Index, right parentheses, returns a substring of the String object beginning at the character at index start Index and ending at the character at index end Index minus 1.
Line 8. Return Value: String. Method name and argument list: substring, left parentheses, int start Index, right parentheses, returns a substring of the String object beginning at the character at index start Index and continuing to the end of the String.
Line 9. Return Value: boolean. Method name and argument list: is Blank, left parentheses, right parentheses, returns true if this String is empty or only contains white space character, left parentheses, including back slash, t, or back slash, n, right parentheses.
Line 10. Return Value: String. Method name and argument list: strip, left parentheses, right parentheses, returns a copy of this String with all the leading and trailing white characters removed, left parentheses, including back slash t, or back slash, n, right parentheses.

Back to Table

The syntax is as follows. object Reference dot method Name, left parentheses, argument list, right parentheses, or, object Reference dot method Name, left parentheses, a r g 1, comma, a r g 2, comma, a r g 2, comma, dot, dot, dot, right parentheses.

Back to Code

The rows are labelled Character and Index. The column entries are as follows.
Column 1. Character: uppercase h. Index: 0.
Column 2. Character: e. Index: 1.
Column 3. Character: l. Index: 2.
Column 4. Character: l. Index: 3.
Column 5. Character: o. Index: 4.

Back to Table

System dot out dot print l n, left parentheses, double quotes, In caps, colon, blank space, double quotes, plus, greeting dot to Upper Case, left parentheses, right parentheses, right parentheses, semicolon.

Back to Code

System dot out dot print l n, left parentheses, double quotes, In caps, colon, blank space, double quotes, plus, double quotes, Good Morning, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, String, int, new, null. Line 1: Forward slash, asterisk. A Demonstration of Trying to Use a Null Object Reference. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Null Reference 2. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: String greeting, equals, new String, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 10, indented twice: int len, equals, greeting dot length, left parentheses, right parentheses, semicolon. Line 11, indented twice: System dot out dot print l n, left parentheses, greeting, plus, double quotes, blank space, has, blank space, double quotes, plus, len, plus, double quotes, blank space, characters, double quotes, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: greeting, equals, null, semicolon. Line 14, indented twice: 2 forward slashes. attempt to use null object reference. Line 15, indented twice: len, equals, greeting dot length, left parentheses, right parentheses, semicolon. Line 16, indented once: right brace. Line 17: right brace.

Back to Example

Program code. The code contains the following keywords: public, class, static, void, String, int, new, null. Line 1: Forward slash, asterisk. A Demonstration of Trying to Use a Null Object Reference. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Null Reference 2. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Back to Figure

Each table has 2 rows labelled Character and Index.
The first table is labelled first Name. The column entries are as follows.
Column 1. Character: lowercase a. Index: 0.
Column 2. Character: lowercase b. Index: 1.
Column 3. Character: lowercase r. Index: 2.
Column 4. Character: lowercase a. Index: 3.
Column 5. Character: lowercase h. Index: 4.
Column 6. Character: lowercase a. Index: 5.
Column 7. Character: lowercase m. Index: 6.
The second table is labelled first Name Start. The column entries are as follows.
Column 1. Character: uppercase a. Index: 0.
An arrow is drawn from the first column of first Name to the first column of first Name start.
The third table is labelled first Name Remainder. The column entries are as follows.
Column 1. Character: lowercase b. Index: 1.
Column 2. Character: lowercase r. Index: 2.

Column 3. Character: lowercase a. Index: 3.
Column 4. Character: lowercase h. Index: 4.
Column 5. Character: lowercase a. Index: 5.
Column 6. Character: lowercase m. Index: 6.
An arrow is drawn from columns 2 to 7 of first Name to first name Remainder.
A plus sign is marked between first Name Start and first Name Remainder.
The fourth table is labelled first Name. The column entries are as follows.
Column 1. Character: uppercase a. Index: 0.
Column 2. Character: lowercase b. Index: 1.
Column 3. Character: lowercase r. Index: 2.
Column 4. Character: lowercase a. Index: 3.
Column 5. Character: lowercase h. Index: 4.
Column 6. Character: lowercase a. Index: 5.
Column 7. Character: lowercase m. Index: 6.
Arrows are drawn from first Name Start and first Name Remainder to first Name.

Back to Figure

The table has 2 columns labelled Package and Categories of Classes. The row entries are as follows.
Row 1. Package: java dot lang. Categories of Classes: Basic functionality common to many programs, such as the String class, Math class, and object wrappers for the primitive data types.
Row 2. Package: java dot text. Categories of Classes: Classes for formatting numeric output.

Row 3. Package: java dot util. Categories of Classes: The Scanner class, the Random class, and other miscellaneous classes.
Row 4. Package: java dot i o. Categories of Classes: Classes for reading from and writing to files.

Line 57, indented twice: Decimal Format big Number, equals, new Decimal Format, left parentheses, double quotes, hash, comma, hash, hash, hash, double quotes, right parentheses, semicolon. Line 58: blank. Line 59, indented twice: int millions, equals, 1234567, semicolon. Line 60, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, millions is, blank space, double quotes. Line 61, indented multiple times: plus, big Number dot format, left parentheses, millions, right parentheses, right parentheses, semicolon. Line 62, indented once: right brace. Line 63: right brace.

Back to Example

Double quotes, dollar sign, 0.00, dollar sign.

Back to Code

The description of the Random class constructor is as follows. Random, left parentheses, right parentheses, creates a random number generator with a seed generated using the system time. The second table describes the next Int method. The table has 2 columns labelled Return Value and Method name and argument list. The row entry is as follows. Return value: int. Method name and argument list: next Int, left parentheses, int number, right parentheses, returns a random integer ranging from 0 up to, but not including, number in uniform distribution.

Back to Table

Program code. The code contains the following keywords: import, public, class, static, void, String, int. Line 1: Forward slash, asterisk. A demonstration of the Random Class. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: import java dot util dot Random, semicolon. Line 5: blank. Line 6:

public class Random Numbers. Line 7: left brace. Line 8, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 9, indented once: left brace. Line 10, indented twice: Random random, equals, new Random, left parentheses, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: 2 forward slashes. simulate the roll of a die. Line 13, indented twice: int die, equals, random dot next Int, left parentheses, 6, right parentheses, plus, 1, semicolon. Line 14, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, The die roll is, blank space, double quotes, plus, die, right parentheses, semicolon. Line 15: blank. Line 16, indented once: 2 forward slashes, generate a random number between 20 and 200. Line 17, indented twice: int start, equals, 20, comma, end, equals, 200, semicolon. Line 18, indented twice: int number, equals, random dot next Int, left parentheses, end minus start plus 1, right parentheses, plus, start, semicolon. Line 19, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, The random number between, blank space, double quotes, plus, start. Line 20, indented multiple times: plus, double quotes, blank space, and, blank space, double quotes, plus, end, plus, double quotes, blank space, is, blank space, double quotes, plus, number, right parentheses, semicolon. Line 21, indented once: right brace. Line 22: right brace.

Back to Example

The syntax of the Scanner class constructor is as follows. Scanner, left parentheses, Input Stream data Source, right parentheses. Creates a Scanner object that will read from the Input Stream data Source. To read from the keyboard, we will use the predefined Input Stream System dot in. The table is titled Selected Methods of the Scanner Class. The table has 2 columns labelled Return Value and Method Name and Argument List. The row entries are as follows.

Row 1. Return Value: byte. Method Name and Argument List: next Byte, left parentheses, right parentheses, returns the next input as a byte.

Row 2. Return Value: short. Method Name and Argument List: next Short, left parentheses, right parentheses, returns the next input as a short.

Row 3. Return Value: int. Method Name and Argument List: next Int, left parentheses, right parentheses, returns the next input as an int.

Row 4. Return Value: long. Method Name and Argument List: next Long, left parentheses, right parentheses, returns the next input as a long.

Row 5. Return Value: float. Method Name and Argument List: next Float, left parentheses, right parentheses, returns the next input as a float.

Row 6. Return Value: double. Method Name and Argument List: next Double, left parentheses, right parentheses, returns the next input as a double.

Row 7. Return Value: boolean. Method Name and Argument List: next Boolean, left parentheses, right

parentheses, returns the next input as a boolean.
Row 8. Return Value: string. Method Name and Argument List: next, left parentheses, right parentheses, returns the next token in the input line as a String.
Row 9. Return Value: string. Method Name and Argument List: next Line, left parentheses, right parentheses, returns the unread characters of the input line as a String.

Back to Table

Program code. The code contains the following keywords: import, public, class, static, void, String, int, float. Line 1: Forward slash, asterisk. A demonstration of reading from the keyboard using Scanner. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class Data Input. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print, left parentheses, double quotes, Enter your first name, right angled bracket, double quotes, right parentheses, semicolon. Line 14, indented twice: String first Name, equals, scan dot next, left parentheses, right parentheses, semicolon. Line 15, indented twice: System dot out dot print l n, left parentheses, double quotes, Your name is, blank space, double quotes, plus, first Name, right paentheses, semicolon. Line 16: blank. Line 17, indented twice: System dot out dot print, left parentheses, double quotes, backslash, n, Enter your age as an integer, right angled bracket, double quotes, right parentheses, semicolon. Line 18, indented twice: int age, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 19, indented twice: System dot out dot print l n, left parentheses, double quotes, Your age is, blank space, double quotes, plus, age, right parentheses, semicolon. Line 20: blank. Line 21, indented twice: System dot out dot print, left parentheses, double quotes, back slash, n, Enter your G P A, right angled bracket, double quotes, right parentheses, semicolon. Line 22, indented twice: float g p a, equals, scan dot next Float, left parentheses, right parentheses, semicolon. Line 23, indented twice: System dot out dot print l n, left parentheses, double quotes, Your G P A is, blank space, double quotes, plus, g p a, right parentheses, semicolon. Line 24, indented once: right brace. Line 25: right brace.

Back to Example

Program code. The code contains the following keywords: import, public, class, static, void, String, new, char. Line 1: Forward slash, asterisk. A demonstration of how to get character input using Scanner. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class

Character Input. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print, left parentheses, double quotes, Enter your middle initial, right angled bracket, blank space, double quotes, right parentheses, semicolon. Line 14, indented twice: String initial S, equals, scan dot next, left parentheses, right parentheses, semicolon. Line 15, indented twice: char initial, equals, initial S dot char At, left parentheses, 0, right parentheses, semicolon. Line 16, indented twice: System dot out dot print l n, left parentheses, double quotes, Your middle initial is, blank space, double quotes, plus, initial, right parentheses, semicolon. Line 17, indented once: right brace. Line 18: right brace.

Back to Example

The table has 2 columns labelled Character and Unicode equivalents. The row entries are as follows.
Row 1. Character: space. Unicode equivalents: back slash, u 0 0 A 0, comma, back slash, u 2 0 0 7, comma, back slash, u 2 0 2 F.
Row 2. Character: tab. Unicode equivalents: back slash, u 0 0 0 9, comma, back slash, u 0 0 0 B.
Row 3. Character: line feed. Unicode equivalents: back

slash, u 0 0 0 A.
Row 4. Character: form feed. Unicode equivalents: back slash, u 0 0 0 C.
Row 5. Character: carriage return. Unicode equivalents: back slash, u 0 0 0 D.
Row 6. Character: file, group, unit, and record separators. Unicode equivalents: back slash, u 0 0 1 C, comma, back slash, u 0 0 1 D, comma, back slash, u 0 0 1 E, comma, back slash, u 0 0 1 F.

Back to Table

Left angled bracket, tab, right angled bracket, Jon, left angled bracket, space, right angled bracket, Olsen, comma, left angled bracket, space, right angled bracket, 21, left angled bracket, space, right angled bracket.

Back to Code

Left angled bracket, space, right angled bracket, left angled bracket, space, right angled bracket, left angled bracket, space, right angled bracket, left angled bracket, tab, right angled bracket, 21, left angled bracket, newline, right angled bracket.

Back to Code

Left angled bracket, tab, right angled bracket, Jon, left angled bracket, space, right angled bracket, Olsen, comma, left angled bracket, space, right angled bracket, 21, left angled bracket, space, right angled bracket.

Back to Code

Program code. The code uses the following keywords: import, public, class, static, void, String. Line 1: Forward slash, asterisk. A demonstration of using Scanner's next Line method. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class Input A Line. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print, left parentheses, double quotes, Enter a sentence, right angled bracket, double quotes, right parentheses, semicolon. Line 14, indented once: String sentence, equals, scan dot next Line, left parentheses, right parentheses, semicolon. Line 15, indented once: System dot out dot print l n, left parentheses, double quotes, You said, colon, back slash, double quotes, double quotes, plus, sentence, plus, double quotes, backslash, double quotes, double quotes, right parentheses, semicolon. Line 16, indented once: right brace. Line 17: right brace.

Back to Example

The first table has 2 columns labelled Constant and value.

The row entries are as follows.

Row 1. Constant: in. Value: Static constant that represents the standard input stream, by default the keyboard.

Row 2. Constant: out. Value: static constant that represents the standard output stream, by default the Java console.

The second table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.

Row 1. Return value: void. Method name and argument list: exit, left parentheses, int exit Status, right parentheses. Static method that terminates the Java Virtual Machine. A value of 0 for exit Status indicates a normal termination. Any other values indicate an abnormal termination and are used to signal that the program ended because an error occurred.

Back to Table

The table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.

Row 1. Return value: void. Method name and argument list: print, left parentheses, argument, right parentheses, prints argument to the standard output device. The argument can be any primitive data type, a String object, or another object reference.

Row 2. Return value: void. Method name and argument list: print l n, left parentheses, argument, right

parentheses, prints argument to the standard output device, then prints a newline character. The argument can be any primitive data type, a String, or another object reference.
Row 3. Return value: void. Method name and argument list: print l n, left parentheses, right parentheses, prints a newline character. This method is useful for skipping a line in the program's output.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, String. Line 1: Forward slash, asterisk. Testing the print and print l n methods. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, Forward slash. Line 4: blank. Line 5: public class Print Demo. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: System dot out dot print l n, left parentheses, double quotes, Combine the arguments using concatenation, double quotes, right parentheses, semicolon. Line 10, indented twice: System dot out dot print l n, left parentheses, double quotes, A double, colon, blank space, double quotes, plus, 23.7, plus, double quotes, comma, and an int, colon, blank space, double quotes, plus, 78, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: System dot out dot print, left parentheses, double quotes, backslash, n, Java is case sensitive, colon, blank space, double quotes, right parentheses, semicolon. Line 13, indented twice: System dot out dot print l n, left parentheses, single quote, a, single quote, plus, double quotes, blank space, is different from, blank space, double quotes, plus, single quote, uppercase a, single quote, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, Create a variable and print its value, double quotes, right parentheses, semicolon. Line 16, indented twice: String s, equals, new String, left parentheses, double quotes, The grade is, double quotes, right parentheses, semicolon. Line 17, indented twice: double grade, equals, 3.81, semicolon. Line 18, indented twice: System dot out dot print l n, left parentheses, s, plus, double quotes, blank space, double quotes, plus, grade, right parentheses, semicolon. Line 19: blank. Line 20, indented twice: System dot exit, left parentheses, 0, right parentheses, semicolon. 2 forward slashes. optional. Line 21, indented once: right brace. Line 22: right brace.

Back to Example

The table has 2 columns labelled Constant and Value. The row entries are as follows.
Row 1: Constant: uppercase e. Value: lowercase e, comma, the base of the natural logarithm.
Row 2: Constant: uppercase PI. Value: pi, comma, the ratio of the circumference of a circle to its diameter.

Back to Table

Line 1: Math dot E. Line 2: Math dot PI.

Back to Code

The table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.
Row 1. Return value: data Type Of Arg. Method name and argument list: a b s, left parentheses, a r g, right parentheses, static method that returns the absolute value of the argument a r g, which can be a double, float, int, or long.
Row 2. Return value: double. Method name and argument list: log, left parentheses, double a r g, right parentheses, static method that returns the natural logarithm, left parentheses, in base e, right parentheses, of its argument, a r g. For example, log, left parentheses, 1, right parentheses, returns 0 and log, left parentheses, Math dot uppercase e, right parentheses returns 1.
Row 3. Return value: data Type Of A r g s. Method name and argument list: min, left parentheses, a r g uppercase a, comma, a r g uppercase b, right parentheses, static method that returns the smaller of the two arguments. The arguments can be doubles, floats, ints or longs.
Row 4. Return value: data Type Of A r g s. Method name and argument list: max, left parentheses, a r g uppercase a, comma, a r g uppercase b, right parentheses, static method that returns the larger of the two arguments. The

arguments can be doubles, floats, ints, or longs.
Row 5. Return value: double. Method name and argument list: p o w, left parentheses, double base, comma, double e x p, right parentheses, static method that returns the value of base raised to the e x p power.
Row 6. Return value: long. Method name and argument list: round, left parentheses, double a r g, right parentheses, static method that returns the closest integer to its argument, a r g.
Row 7. Return value: double. Method name and argument list: s q r t, left parentheses, double a r g, right parentheses, static method that returns the positive square root of a r g.

Back to Table

Math dot a b s, left parentheses, negative 5, right parentheses.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, String, double. Line 1: Forward slash, asterisk. A demonstration of the Math class methods and constants. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Math Constants. Line 6: left brace Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once:

left brace. Line 9, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of e is, blank space, double quotes, plus, Math dot E, right parentheses, semicolon. Line 11, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of pi is, blank space, double quotes, plus, Math dot PI, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: double d 1, equals, Math dot a b s, left parentheses, 6.7, right parentheses, semicolon. 2 forward slashes, d 1 will be assigned 6.7. Line 13, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, The absolute value of 6.7 is, blank space, double quotes, plus, d 1, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: double d 2, equals, Math dot a b s, left parentheses, negative 6.7, right parentheses, semicolon. 2 forward slashes, d 2 will be assigned 6.7. Line 16, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, The absolute value of negative 6.7 is, blank space, double quotes, plus, d 2, right parentheses, semicolon. Line 17, indented once: right brace. Line 18: right brace.

Back to Example

Program code. The code contains the following keywords: public, class, static, void, string, double. Line 1: Forward slash, asterisk. A demonstration of some Math class methods. Line 14: blank. Line 15, indented twice: int sum, equals, int Primitive, plus, integer Object, semicolon. Line 16, indented twice:

System dot out dot print l n, left parentheses, double quotes, Their sum is, blank space, double quotes, plus, sum, right parentheses, semicolon. Line 17: blank. Line 18, indented twice: int i 1, equals, Integer dot parse Int, left parentheses, double quotes, 76, double quotes, right parentheses, semicolon. 2 forward slashes, convert double quotes, 76, double quotes, to an int. Line 19, indented twice: Integer i 2, equals, Integer dot value Of, left parentheses, double quotes, 76, double quotes, right parentheses, semicolon. 2 forward slashes, convert, double quotes, 76, double quotes, to Integer. Line 20, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash, n, The value of i 1 is, blank space, double quotes, plus, i 1, right parentheses, semicolon. Line 21, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of i 2 is, blank space, double quotes, plus, i 2, right parentheses, semicolon. Line 22: blank. Line 23, indented twice: double d 1, equals, Double dot parse Double, left parentheses, double quotes, 58.32, double quotes, right parentheses, semicolon. Line 24, indented twice: Double d 2, equals, Double dot value Of, left parentheses, double quotes, 58.32, double quotes, right parentheses, semicolon. Line 25, indented twice: System dot out dot print l n, left parentheses, double quotes, backslash n, The value of d 1 is, blank space, double quotes, plus, d 1, right parentheses, semicolon. Line 26, indented twice: System dot out dot print l n, left parentheses, double quotes, The value of d 2 is, blank space, double quotes, plus, d 2, right parentheses, semicolon. Line 27, indented once: right brace. Line 28: right brace.

Back to Example

The first table is titled Useful methods of the Integer Wrapper Class. The table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.
Row 1. Return value: int. Method name and argument list: parse Int, left parentheses, String s, right parentheses, static method that converts the String s to an int and returns that value.
Row 2. Return value: Integer. Method name and argument list: value Of, left parentheses, String s, right parentheses, static method that converts the String s to an Integer object and returns that object.
The second table is titled Useful methods of the Double wrapper class. The table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.
Row 1. Return value: double. Method name and argument list: parse Double, left parentheses, String s, right parentheses, static method that converts the String s to a double and returns that value.
Row 2. Return value: Double. Method name and argument list: value Of, left parentheses, String s, right parentheses, static method that converts the String s to a Double object and returns that object.

Back to Table

The table is titled useful static methods of the character wrapper class. The table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.
Row 1. Return value: boolean. Method name and argument list: is Digit, left parentheses, char c, right parentheses, returns true if c is a character from, single quote, 0, single quote, to single quote, 9, single quote, or a digit in other languages; false, otherwise.
Row 2. Return value: boolean. Method name and argument list: is Letter, left parentheses, char c, right parentheses, returns true if c is a letter; false, otherwise.
Row 3. Return value: boolean. Method name and argument list: is Lower Case, left parentheses, char c, right parentheses, returns true if c is a lowercase letter; false, otherwise.
Row 4. Return value: boolean. Method name and argument list: is Upper Case, left parentheses, char c, right parentheses, returns true if c is an uppercase letter; false, otherwise.
Row 5. Return value: char. Method name and argument list: to Lower Case, left parentheses, char c, right parentheses, returns the lowercase version of c if c is a letter; otherwise it returns c unchanged.
Row 6. Return value: char. Method name and argument list: to Upper Case, left parentheses, char c, right parentheses, returns the uppercase version of c if c is a

letter; otherwise it returns c unchanged.

Back to Code

2 forward slashes, your code goes here.

Back to Code

Line 1: String s equals double quotes, Hello World, double quotes, semicolon.
Line 2: System dot out dot print l n, left parentheses, s, right parentheses, semicolon.

Back to Code

Line 1: String s equals String, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.
Line 2: System dot out dot print l n, left parentheses, s, right parentheses, semicolon.

Back to Code

Line 1: String s 1 equals double quotes, Hello, double quotes, semicolon. In the string Hello, character h is in uppercase.
Line 2: String s 2 equals double quotes, e l l o, double quotes, semicolon.
Line 3: String s equals s 1 minus s 2, semicolon.

Back to Code

Line 1: short s equals Math dot round, left parentheses, 3.2, right parentheses, semicolon.

Line 2: System dot out dot print l n, left parentheses, s, right parentheses, semicolon.

Back to Code

Line 1: int a equals Math dot p o w, left parentheses, 3, comma, 4, right parentheses, semicolon.
Line 2: System dot out dot print l n, left parentheses, a, right parentheses, semicolon.

Back to Code

Line 1: double pi equals Math, left parentheses, uppercase p uppercase i, right parentheses, semicolon.
Line 2: System dot out dot print l n, left parentheses, pi, right parentheses, semicolon.

Back to Code

Line 1: String s equals, single quote, uppercase h, single quote, semicolon.
Line 2: System dot out dot print l n, left parentheses, double quotes, s is, blank space, double quotes, plus s, right parentheses, semicolon.

Back to Code

Program code. The words in the variable names are merged. The code contains the following keywords: public, class, static, void, main, String, int.
Line 1: public class Test.
Line 2: left brace.

Line 3, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses.
Line 4, indented once: left brace.
Line 5, indented twice: int a equals 6, semicolon.
Line 6, indented twice: Number Format n f equals Number Format dot get Currency Instance, left parentheses, right parentheses, semicolon.
Line 7, indented once: right brace.
Line 8: right brace.

Back to Code

The compiler message is as follows.
Line 1: Test dot java, colon, 6, colon, error, colon, cannot find symbol.
Line 2, indented once: Number Format n f equals Number Format dot get Currency Instance, left parentheses, right parentheses, semicolon.
Line 3: a caret sign below uppercase N of the first occurrence of Number Format in Line 2.
Line 4, indented once: symbol, colon, class Number Format.
Line 5, indented once: location, colon, class Test.
Line 6: Test dot java, colon, 6, colon, error, colon, cannot find symbol.
Line 7, indented once: Number Format n f equals Number Format dot get Currency Instance, left parentheses, right parentheses, semicolon.
Line 8: a caret sign below uppercase N of the second

occurrence of Number Format in Line 7.
Line 9, indented once: symbol, colon, variable Number Format.
Line 10, indented once: location, colon, class Test.
Line 11: 2 errors.

Back to Code

The code sequence has 3 lines which are as follows.
Line 1: String s, semicolon. 2 forward slashes, line 10.
Line 2: int l equals s dot length, left parentheses, right parentheses, semicolon. 2 forward slashes, line 11.
Line 3: System dot out dot print l n, left parentheses, double quotes, length is, blank space, double quotes, plus, l, right parentheses, semicolon. 2 forward slashes, line 12.

Back to Code

The compiler message is as follows.
Line 1: Test dot java, colon, 11, colon, error, colon, variable s might not have been initialized.
Line 2, indented once: int l equals s dot length left parentheses, right parentheses, semicolon, 2 forward slashes, line 11.
Line 3: a caret sign below lowercase s in Line 2.
Line 4: 1 error.

Back to Code

The code sequence has 2 lines which are as follows.

Line 1: double d equals math dot s q r t, left parentheses, 6, right parentheses, semicolon, 2 forward slashes, line 10.
Line 2: System dot out dot print l n, left parentheses, double quotes, d equals, double quotes, plus d, right parentheses, semicolon, 2 forward slashes, line 11.

Back to Code

The compiler message is as follows.
Line 1: Test dot java, colon, 10, colon, error, colon, cannot find symbol.
Line 2, indented once: double d equals math dot s q r t, left parentheses, 6, right parentheses, semicolon, 2 forward slashes, line 10.
Line 3: a caret sign below lowercase m of Line 2.
Line 4, indented once: symbol, colon, variable math.
Line 5, indented once: location, colon, class Test.
Line 6: 1 error.

Back to Code

The code sequence has 2 lines which are as follows.
Line 1: double d equals Math dot PI, left parentheses, right parentheses, semicolon. 2 forward slashes, line 10.
Line 2: System dot out dot print l n, left parentheses, double quotes, d equals double quotes, plus d, right parentheses, semicolon. 2 forward slashes, line 11.

Back to Code

The compiler message is as follows.
Line 1: Test dot java, colon, 10, colon, error, colon, cannot find symbol.
Line 2, indented once: double d equals Math dot PI, left parentheses, right parentheses, semicolon. 2 forward slashes, line 10.
Line 3: a caret sign below the dot in Line 2.
Line 4, indented once: symbol, colon, method PI, left parentheses, right parentheses.
Line 5, indented once: location, colon, class Math.
Line 6: 1 error.

Back to Code

The code sequence has 2 lines which are as follows.
Line 1: double d equals Math dot e, semicolon. 2 forward slashes, line 10
Line 2: System dot out dot print l n, left parentheses, double quotes, d, equals, double quotes, plus d, right parentheses, semicolon. 2 forward slashes, line 11.

Back to Code

The compiler message is as follows.
Line 1: Test dot java, colon, 10, colon, error, colon, cannot find symbol.
Line 2, indented once: double d equals Math dot e, semicolon.
Line 3: a caret sign below dot in Line 2.
Line 4, indented once: symbol, colon, variable e.

Line 5, indented once: location, colon, class Math.
Line 6: 1 error.

Back to Code

The code sequence has 3 statements which are as follows.
Line 1: double grade equals .895, semicolon.
Line 2: Decimal Format percent equals.
Line 3, indented once: new Decimal Format, left parentheses, double quotes, hash, dot, 0, percent, double quotes, right parentheses, semicolon.
Line 4: blank.
Line 5: System dot out dot print l n, left parentheses, double quotes, Your grade is, blank space, double quotes, plus, grade, right parentheses, semicolon.

Back to Code

The expected output is as follows. Your grade is 89.5 percent.

Back to Code

The actual output is as follows. Your grade is 0.895.

Back to Code

Line 1: area equals pi asterisk r to the power of 2. Line 2: circumference equals 2 asterisk pi asterisk r.

Back to Equation

Line 1: x 1 equals left parentheses, minus sign, b, plus, square root, left parentheses, b squared minus 4 a c, right parentheses, right parentheses, forward slash, left parentheses, a, right parentheses. Line 2: x 2 equals left parentheses, minus sign, b, minus square root, left parentheses, b squared minus 4 a c, right parentheses, right parentheses, forward slash, left parentheses, a, right parentheses.

Back to Equation

Line 1: a equals 1.0, comma, b equals 3.0, comma, c equals 2.0. Line 2: a equals 0.5, comma, b equals 0.5, comma, c equals 0.125. Line 3: a equals 1.0, comma, b equals 3.0, comma, c equals 10.0.

Back to Equation

Program code. The code contains the following keywords: import, public, class, static, String, int, return. Line 1: Forward slash, asterisk, J I Graphics Utility. Line 2, indented once: Utility class for building Java F X graphics applications. Line 3, indented once: Anderson, comma, Franceschi. Line 4: asterisk, forward slash. Line 5: blank. Line 6: import java f x dot scene dot Group, semicolon. Line 7: import java f x dot scene dot canvas dot Canvas, semicolon. Line 8: import java f x dot scene dot canvas dot Graphics Context, semicolon. Line 9: import java f x dot scene dot Scene, semicolon. Line 10: import java f x dot stage dot Stage, semicolon. Line 11: blank. Line 12:

public class J I Graphics Utility. Line 13: left brace. Line 14, indented once: public static Graphics Context set Up Graphics, left parentheses, Stage stage, comma. Line 15, indented multiple times: String title, comma, int height, comma, int width, right parentheses. Line 16, indented once: left brace. Line 17, indented twice: stage dot set Title, left parentheses, title, right parentheses, semicolon. Line 18, indented twice: Canvas canvas, equals, new Canvas, left parentheses, height, comma, width, right parentheses, semicolon. Line 19, indented twice: Graphics Context g c, equals, canvas dot get Graphics Context 2 D, left parentheses, right parentheses, semicolon. Line 20, indented twice: Group root, equals, new Group, left parentheses, canvas, right parentheses, semicolon. Line 21, indented twice: stage dot set Scene, left parentheses, new Scene, left parentheses, root, right parentheses, right parentheses, semicolon. Line 22, indented twice: stage dot show, left parentheses, right parentheses, semicolon. Line 23, indented twice: return g c, semicolon. Line 24, indented once: right brace. Line 25: right brace.

Back to Example

The table has 2 columns labelled Return value and Method name and argument list. The row entry is as follows.
Row 1: Return value: Graphics Context. Method name and argument list: set Up Graphics, left parentheses, Stage stage, comma, String title, comma, int width,

comma, int height, right parentheses, initializes a scene on the stage, sets the title of the window to title, and adds a canvas with the width and height specified, semicolon, returns a Graphics Context object.

Back to Table

Program code. The code contains the following keywords: import, public, class, extends, at symbol override, void, static, String. Line 1: Forward slash, asterisk, A Shell for creating graphics applications. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java f x dot application dot Application, semicolon. Line 6: import java f x dot scene dot canvas dot Graphics Context, semicolon. Line 7: import java f x dot stage dot Stage, semicolon. Line 8: blank. Line 9: public class Shell Graphics Application extends Application. Line 10: left brace. Line 11, indented once: at symbol, override. Line 12, indented once: public void start, left parentheses, Stage stage, right parentheses. Line 13, indented once: left brace. Line 14, indented twice: 2 forward slashes, set up window title and size. Line 15, indented twice: Graphics Context g c, equals, J I Graphics Utility dot set Up Graphics, left parentheses. Line 16, indented multiple times: stage, comma, double quotes, Shell Graphics Application, double quotes, comma, 700, comma, 400, right parentheses, semicolon. Line 17: blank. Line 18, indented twice: 2 forward slashes, your drawing code goes here. Line 19, indented once: right brace. Line 20: blank. Line

21, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 22, indented once: left brace. Line 23, indented twice: launch, left parentheses, a r g s, right parentheses, semicolon. Line 24, indented once: right brace. Line 25: right brace.

Back to Code

The table has 2 columns labeled Return Value and Method name and argument list. The row entries are as follows. Row 1. Return Value: void. Method name and argument list: set Stroke, left parentheses, Paint color, right parentheses, sets the current outline color to color. Row 2. Return value: void. Method name and argument list: set Fill, left parentheses, Paint color, right parentheses, sets the current fill color to color.

Back to Table

The table has 4 columns labeled Color Constant, Red, Green, and Blue. The row entries are as follows. Row 1. Color Constant: a black square is shown and the color constant is Color dot BLACK. Red: 0 0. Green: 0 0. Blue: 0 0. Row 2. Color Constant: a blue square is shown and the color constant is Color dot BLUE. Red: 0 0. Green: 0 0. Blue: F F. Row 3. Color Constant: a cyan square is shown and the color constant is Color dot CYAN. Red: 0 0. Green: F F. Blue: F F. Row 4. Color Constant: a dark gray square is shown and the color constant is Color dot DARK GRAY. Red: A 9. Green: A 9. Blue: A 9. Row 5. Color Constant: a gray square is shown and the color constant is Color dot GRAY. Red: 8 0. Green: 8 0. Blue: 8 0. Row 6. Color Constant: a green square is shown and the color constant is Color dot GREEN. Red: 0 0. Green: F F. Blue: 0 0. Row 7. Color Constant: a light gray square is shown and the color constant is color dot LIGHT GRAY. Red: D 3. Green: D 3. Blue: D 3. Row 8. Color Constant: a magenta square is shown and the color constant is Color dot MAGENTA. Red: F F. Green: 0 0. Blue: F F. Row 9. Color Constant: an orange square is shown and the color constant is Color dot ORANGE. Red: F F. Green: A 5. Blue: 0 0. Row 10. Color Constant: a pink square is shown and the color constant is Color dot PINK. Red: F F. Green: C 0. Blue: C B. Row 11. Color Constant: a red square is shown and the color constant is Color dot RED. Red: F F. Green: 0 0. Blue: 0 0. Row 12. Color Constant: a white square is shown and the color constant is Color dot WHITE. Red: F F. Green: F F. Blue: F F. Row 13. Color Constant: a yellow square is shown and the color constant is Color dot YELLOW. Red: F F. Green: F F. Blue: 0 0.

Back to Table

The table has 2 columns labeled Return Value and Method name and argument list. The row entry is as follows. Row 1. Return value: Color. Method name and argument list: r g b, left parentheses, int r r, comma, int g g, comma, int b b, right parentheses, creates a color object with an r r red component, g g green component and b b blue component.

Back to Table

The table has 2 columns labelled Return Value and Method name and argument list. The row entries are as follows.
Row 1. Return Value: void. Method name and argument list: stroke Line, left parentheses, double x Start, comma, double y Start, comma, double x End, comma, double y End, right parentheses, draws a line starting at, left parentheses, x Start, comma, y Start, right parentheses,

and ending at left parentheses, x End, comma, y End, right parentheses.
Row 2. Return Value: void. Method name and argument list: stroke R e c t, left parentheses, double x, comma, double y, comma, double width, comma, double height, right parentheses, draws the outline of a rectangle with its top left corner at left parentheses, x, comma, y, right parentheses, with the specified width and height in pixels.
Row 3. Return Value: void. Method name and argument list: fill R e c t, left parentheses, double x, comma, double y, comma, double width, comma, double height, right parentheses, draws a solid rectangle with its top left corner at, left parentheses, x, comma, y, right parentheses, with the specified width and height in pixels.
Row 4. Return Value: void. Method name and argument list: clear R e c t, left parentheses, double x, comma, double y, comma, double width, comma, double height, right parentheses, draws a solid rectangle in the current background color with its top left corner at left parentheses, x, comma, y, right parentheses, with the specified width and height in pixels.
Row 5. Return Value: void. Method name and argument list: stroke Oval, left parentheses, double x, comma, double y, comma, double width, comma, double height, right parentheses, draws the outline of an oval inside an invisible bounding rectangle with the specified width and height in pixels, semicolon, the top left corner of the bounding rectangle is, left parentheses, x, comma, y, right parentheses.

Row 6. Return Value: void. Method name and argument list: fill Oval, left parentheses, double x, comma, double y, comma, double width, comma, double height, right parentheses, draws a solid oval inside an invisible bounding rectangle with the specified width and height in pixels, semicolon, the top left corner of the bounding rectangle is left parentheses, x, comma, y, right parentheses.

Row 7. Return Value: void. Method name and argument list: stroke Text, left parentheses, String s, comma, double x, comma, double y, right parentheses, displays the string s with the left parentheses, x, comma, y, right parentheses, coordinate indicating the lower left corner of the first character, semicolon, the text is drawn in the current stroke color and line width.

Row 8. Return Value: void. Method name and argument list: fill Text, left parentheses, String s, comma, double x, comma, double y, right parentheses, displays the String s with the left parentheses, x, comma, y, right parentheses, coordinate indicating the lower left corner of the first character, semicolon, the text is drawn in the current fill color.

Row 9. Return Value: void. Method name and argument list: set Line Width, left parentheses, double width, right parentheses, sets the current stroke line width to width pixels.

Row 10. Return Value: void. Method name and argument list: set Font, left parentheses, Font f, right parentheses, sets the font to f for displaying text.

Back to Table

Program code. The code contains the following keywords: import, public, class, extends, at symbol override, void, final, int. Line 1: Forward slash, asterisk, Drawing Lines. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java f x dot application dot Application, semicolon. Line 6: import java f x dot scene dot canvas dot Graphics Context, semicolon. Line 7: import java f x dot scene dot paint dot Color, semicolon. Line 8: import java f x dot stage dot Stage, semicolon. Line 9: blank. Line 10: import java dot util dot Random, semicolon. Line 11: blank. Line 12: public class Drawing Lines extends Application. Line 13: left brace. Line 14, indented once: at symbol, Override. Line 15, indented once: public void start, left parentheses, Stage stage, right parentheses. Line 16, indented once: left brace. Line 17, indented twice: final int WIDTH, equals, 700, semicolon. Line 18, indented twice: final int HEIGHT, equals, 400, semicolon. Line 19, indented twice: 2 forward slashes, set up window title and size. Line 20, indented twice: Graphics Context g c, equals, J I Graphics Utility dot set Up Graphics, left parentheses. Line 21, indented multiple times: stage, comma, double quotes, Drawing Lines, double quotes, comma, WIDTH, comma, HEIGHT, right parentheses, semicolon. Line 22: blank. Line 23, indented twice: 2 forward slashes, draw a vertical black line. Line 24, indented twice: g c dot stroke Line, left parentheses, 100, comma, 125, comma, 100, comma, 300, right parentheses, semicolon. Line 25: blank. Line 26, indented twice: 2 forward slashes, draw a horizontal red line. Line 27, indented twice: g c dot set Stroke, left parentheses, Color dot RED, right parentheses, semicolon. Line 28, indented twice: g c dot set Line Width, left parentheses, 5, right parentheses, semicolon. 2 forward slashes, widen the line. Line 29, indented twice: g c dot stroke Line, left parentheses, 300, comma, 75, comma, 550, comma, 75, right parentheses, semicolon. Line 30: blank. Line 31, indented twice: 2 forward slashes, draw a diagonal line in a random color. Line 32, indented twice: Random rand, equals, new Random, left parentheses, right parentheses, semicolon. Line 33, indented twice: int red, equals, rand dot next Int, left parentheses, 0 x F F, right parentheses, semicolon. Line 34, indented twice: int green, equals, rand dot next Int, left parentheses, 0 x F F, right parentheses, semicolon. Line 35, indented twice: int blue, equals, rand dot next Int, left parentheses, 0 x F F, right parentheses, semicolon. Line 36, indented twice: Color random Color, equals, Color dot r g b, left parentheses, red, comma, green, comma, blue, right parentheses, semicolon. Line 37, indented twice: g c dot set Stroke, left parentheses, random Color, right parentheses, semicolon. Line 38: blank. Line 39, indented twice: g c dot stroke Line, left parentheses, 0, comma, 0, comma, WIDTH minus 1, comma, HEIGHT minus 1, right parentheses, semicolon. Line 40, indented once: right brace. Back to Example

The table has 2 columns labeled Return Value and Method Name and Argument List. The row entries are as follows. Row 1. Return Value: void. Method Name and Argument List: begin Path, left parentheses, right parentheses, sets the drawing path to empty. Row 2. Return Value: void. Method Name and Argument List: move To, left parentheses, double x, comma, double y, right parentheses, moves to the, left parentheses, x, comma, y, right parentheses, location without adding a line to the path. Row 3. Return Value: void. Method Name and Argument List: line To, left parentheses, double x, comma, double y, right parentheses, adds a line to the current path from the previous location to, left parentheses, x, comma, y, right parentheses. Row 4. Return Value: void. Method Name and Argument List: close Path, left parentheses, right parentheses, closes the path by adding a line from the previous location to the first location of the path. Row 5. Return Value: void. Method Name and Argument List: stroke, left parentheses, right parentheses, draws the path using the current stroke color. Row 6. Return Value: void. Method Name and Argument List: fill, left parentheses, right parentheses, draws the path using the current fill color.

Line 14, indented once: left brace.
Line 15, indented twice: launch, left parentheses, a r g s, right parentheses, semicolon.
Line 16, indented once: right brace.
Line 17: right brace.

Back to Code

The statement is as follows. Color c equals Color dot r g b, left parentheses, 1.4, comma, 234, comma, 23, right parentheses, semicolon. 2 forward slashes. line 10.

Back to Code

The compiler message is as follows.
Line 1: My Application dot java, colon, 10, colon, error, colon, incompatible types, colon, possible.
Line 2: lossy conversion from double to int.
Line 3: Color c equals Color dot r g b, left parentheses, 1.4, comma, 234, comma, 23, right parentheses, semicolon. 2 forward slashes. line 10.
Line 4: A caret sign under 1.4 in Line 3.
Line 5: 1 error.

Back to Code

The statement is as follows. Color c equals Color dot Blue, semicolon. 2 forward slashes. line 10.

Back to Code

The compiler message is as follows.
Line 1: My Application dot java, colon, 10, colon, error, colon, cannot find symbol.
Line 2, indented once: Color c equals Color dot Blue, semicolon. 2 forward slashes. line 10.
Line 3: a caret sign under the dot in Line 2.
Line 4: symbol, colon, variable Blue.
Line 5: location, colon, class Color.
Line 6: 1 error.

Back to Code

The table has 3 columns labeled Equality Operator, Type, and Meaning. The row entries are as follows. Row 1.

Equality Operator: 2 equals sign. Type: binary. Meaning: is equal to. Row 2. Equality Operator: exclamation mark, equals sign. Type: binary. Meaning: is not equal to.

Back to Table

The table has 3 columns labeled Relational Operator, Type, and Meaning. The row entries are as follows. Row 1. Relational Operator: less than sign. Type: binary. Meaning: is less than. Row 2. Relational Operator: less than or equal to. Type: binary. Meaning: is less than or equal to. Row 3. Relational Operator: greater than sign. Type: binary. Meaning: is greater than. Row 4. Relational Operator: greater than or equal to. Type: binary. Meaning: is greater than or equal to.

Back to Table

The expression, left parentheses, age less than 32, right parentheses, will evaluate to false. The expression, left parentheses, age less than or equal to 32, right parentheses, will evaluate to true. The expression, left parentheses, age greater than 32, right parentheses, will evaluate to false, and. The expression, left parentheses, age greater than or equal to 32, right parentheses, will evaluate to true.

Back to Code

The table has 3 columns labeled Logical Operator, Type, and Meaning. The row entries are as follows.

Row 1. Logical Operator: exclamation mark. Type: unary. Meaning: NOT.
Row 2. Logical Operator: 2 ampersand signs. Type: binary. Meaning: AND.
Row 3. Logical Operator: 2 pipes. Type: binary. Meaning: OR.

Back to Table

The table has 2 columns labeled Operands and Operations. The column labeled Operands is subdivided into 2 columns which are labeled a and b. The column labeled Operations is divided into 3 columns which are labelled exclamation mark a, a 2 ampersand signs b, and a 2 pipes b. The row entries are as follows.
Row 1. a: true. b: true. exclamation mark a: false. a 2 ampersand signs b: true. a 2 pipes b: true.
Row 2. a: true. b: false. exclamation mark a: false. a 2 ampersand signs b: false. a 2 pipes b: true.
Row 3. a: false. b: true. exclamation mark a: true. a 2 ampersand signs b: false. a 2 pipes b: true.
Row 4. a: false. b: false. exclamation mark a: true. a 2 ampersand signs b: false. a 2 pipes b: false.

Back to Table

Row 1. Operator Hierarchy: left parentheses, right parentheses. Order of Same Statement Evaluation: left to right. Operation: parentheses for explicit grouping.
Row 2. Operator Hierarchy: plus plus, minus minus. Order

of Same Statement Evaluation: right to left. Operation: shortcut post increment or post decrement.
Row 3. Operator Hierarchy: plus plus, minus minus, exclamation mark. Order of Same Statement Evaluation: right to left. Operation: shortcut pre increment or pre decrement, logical unary NOT.
Row 4. Operator Hierarchy: asterisk, forward slash, percentage sign. Order of Same Statement Evaluation: left to right. Operation: multiplication, division, modulus.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, int, boolean. Line 1: forward slash, asterisk, Using Logical Operators. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: public class Logical Operators. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: int age, equals, 75, semicolon. Line 10, indented once: boolean test, semicolon. Line 11: blank. Line 12, indented once: test, equals, left parentheses, age greater than 18, ampersand, ampersand, age less than 65, right parentheses, semicolon. Line 13, indented once: System dot out dot print l n, left parentheses, age, plus, double quotes, right angled bracket, 18, ampersand, ampersand, double quotes, plus, age, plus, double quotes, left angled bracket, 65 is, double quotes, plus, test, right parentheses, semicolon. Line 14: blank. Line 15, indented once: 2 forward slashes. short circuitry with AND. Line 16, indented once: test, equals, left parentheses, age, less than, 65, ampersand, ampersand, age, greater than, 18, right parentheses, semicolon. Line 17, indented once: System dot out dot print l n, left parentheses, age, plus, double quotes, left angled bracket, 65, ampersand, ampersand, double quotes, plus, age, plus, double quotes, right angled bracket, 18 is, double quotes, plus, test, right parentheses, semicolon. Line 18: blank. Line 19, indented once: 2 forward slashes, short circuitry with OR. Line 20, indented once: test, equals, left parentheses, age, greater than, 65, 2 pipes, age less than 18, right parentheses, semicolon. Line 21, indented once: System dot out dot print l n, left parentheses, age, plus, double quotes, right angled bracket, 65, 2 pipes, double quotes, plus, age, plus, double quotes, left angled bracket, 18 is, double quotes, plus, test, right angled bracket, semicolon. Line 22: blank. Line 23, indented once: 2 forward slashes, AND has higher precedence than OR. Line 24, indented once: test, equals, left parentheses, age greater than 65, 2 pipes, age less than 18, 2 ampersands, false, right parentheses, semicolon. Line 25, indented once: System dot out dot print l n, left parentheses, age, plus, double quotes, right angled bracket, 65, 2 pipes, double quotes, plus, age. Line 26, indented multiple times: plus, double quotes, left angled bracket, 18, 2 ampersands, false is, double quotes, plus, test, right parentheses, semicolon. Line 27: blank. Line

28, indented once: 2 forward slashes, use of parentheses to force order of execution. Line 29, indented once: test, equals, left parentheses, left parentheses, age greater than 65, 2 pipes, age less than 18, right parentheses, 2 ampersands, false, right parentheses, semicolon. Line 30, indented once: System dot out dot print l n, left parentheses, double quotes, left parentheses, double quotes, plus, age, plus, double quotes, right angled bracket, 65, 2 pipes, double quotes, plus, age. Line 31, indented multiple times: plus, double quotes, left angled bracket, 18, right parentheses, 2 ampersands, false is, double quotes, plus, test, right parentheses, semicolon. Line 32, indented once: right brace. Line 33: right brace.

Back to Example

x, left angled bracket, y, 2 ampersand signs, z. 2 forward slashes. incorrect comparison of x to y and z.

Back to Code

x, left angled bracket, y, 2 ampersand signs, x, left angled bracket, z.

Back to Code

The table has 2 columns labelled Equivalent Expressions and English Meaning. The row entries are as follows. Row 1. Equivalent Expressions: left parentheses, flag 1, 2 equals sign, false, right parentheses, 2 pipes, left parentheses, flag 2, 2 equals sign, false, right

parentheses. English Meaning: flag 1 is false OR flag 2 is false.
Row 2. Equivalent Expressions: exclamation mark, flag 1, 2 pipes, exclamation mark, flag 2. English Meaning: exclamation mark flag 1 is true OR exclamation mark flag 2 is true.
Row 3. Equivalent Expressions: exclamation mark, left parentheses, flag 1, 2 ampersand signs, flag 2, right parentheses. English Meaning: not both flag 1 and flag 2 are true.

Back to Table

The first law is as follows. 1. NOT, left parentheses, A AND B, right parentheses, equals sign, left parentheses, NOT A, right parentheses, OR, left parentheses, NOT B, right parentheses. The second law is as follows. 2. NOT, left parentheses, A OR B, right parentheses, equals, left parentheses, NOT A, right parentheses, AND, left parentheses, NOT B, right parentheses.

Back to Code

exclamation mark, left parentheses, a, 2 ampersand signs, b, right parentheses, is equivalent to, exclamation mark, a, 2 pipes, exclamation mark b.

Back to Code

exclamation mark, left parentheses, a, 2 pipes, b, right parentheses, is equivalent to, exclamation mark, a, 2 ampersand signs, exclamation mark, b.

Back to Code

The table has 10 columns labelled a, b, exclamation mark a, exclamation mark b, a 2 ampersand signs b, a 2 pipes b, exclamation mark, left parentheses, a, 2 ampersand signs, b, right parentheses, exclamation mark 1, 2 pipes, exclamation mark b, exclamation mark, left parentheses, a, 2 pipes, b, right parentheses, exclamation mark a, 2 ampersand signs, exclamation mark b. The row entries are as follows.
Row 1. a: true. b: true. exclamation mark a: false. exclamation mark b: false. a 2 ampersand signs b: true. a 2 pipes b: true. exclamation mark, left parentheses, a 2 ampersand signs b, right parentheses: false. exclamation mark a 2 pipes, exclamation mark b: false. exclamation mark, left parentheses, a 2 pipes, b, right parentheses: false. exclamation mark a 2 ampersand signs exclamation mark b: false.
Row 2. a: true. b: false. exclamation mark a: false. exclamation mark b: true. a 2 ampersand signs b: false. a 2 pipes b: true. exclamation mark, left parentheses, a 2 ampersand signs b, right parentheses: true. exclamation mark a 2 pipes, exclamation mark b: true. exclamation mark, left parentheses, a 2 pipes, b, right parentheses: false. exclamation mark a 2 ampersand signs exclamation mark b: false.
Row 3. a: false. b: true. exclamation mark a: true. exclamation mark b: false. a 2 ampersand signs b: false.

a 2 pipes b: true. exclamation mark, left parentheses, a 2 ampersand signs b, right parentheses: true. exclamation mark a 2 pipes, exclamation mark b: true. exclamation mark, left parentheses, a 2 pipes, b, right parentheses: false. exclamation mark a 2 ampersand signs exclamation mark b: false.
Row 4. a: false. b: false. exclamation mark a: true. exclamation mark b: true. a 2 ampersand signs b: false. a 2 pipes b: false. exclamation mark, left parentheses, a 2 ampersand signs b, right parentheses: true. exclamation mark a 2 pipes, exclamation mark b: true. exclamation mark, left parentheses, a 2 pipes, b, right parentheses: true. exclamation mark a 2 ampersand signs exclamation mark b: true.

Back to Table

The table has 2 columns labelled Expression and exclamation mark, left parentheses, expression, right parentheses. The row entries are as follows.
Row 1. Expression: a 2 equals sign b. exclamation mark, left parentheses, Expression, right parentheses: a exclamation mark equals sign b.
Row 2. Expression: a exclamation mark equal sign b. exclamation mark, left parentheses, Expression, right parentheses: a 2 equals sign b.
Row 3. Expression: a left angled bracket b. exclamation mark, left parentheses, Expression, right parentheses: a right angled bracket equals sign b.
Row 4. Expression: a right angled bracket equals sign b.

exclamation mark, left parentheses, Expression, right parentheses: a left angled bracket b.
Row 5. Expression: a right angled bracket b. exclamation mark, left parentheses, Expression, right parentheses: a left angled bracket equals sign b.
Row 6. Expression: a left angled bracket equals sign b. exclamation mark, left parentheses, Expression, right parentheses: a right angled bracket b.

Back to Table

The table has 2 columns labelled Equivalent Expressions and English Meaning. The row entries are as follows.
Row 1. Equivalent Expressions: left parentheses, age, left angled bracket, equals sign, 18, 2 pipes, age, right angled bracket, equals sign, 65, right angled bracket. English Meaning: age is less than or equal to 18 or age is greater than or equal to 65.
Row 2. Equivalent Expressions: exclamation mark, left parentheses, age, right angled bracket, 18, 2 ampersand signs, age, left angled bracket, 65, right angled bracket. English Meaning: age is not between 18 and 65.
Row 3. Equivalent Expressions: exclamation mark, left parentheses, age, right angled bracket, 18, right parentheses, 2 pipes, exclamation mark, left parentheses, age, left angled bracket, 65, right angled bracket. English Meaning: age is not greater than 18 or age is not less than 65.

Back to Table

The pattern is as follows. Line 1: if, left parentheses, condition, right parentheses. Line 2: left brace. Line 3, indented once: true block. Line 4: right brace. Line 5: next statement.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, int, if. Line 1: forward slash, asterisk, Using if to calculate a final test grade. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: import java dot util dot Scanner, semicolon. Line 5: blank. Line 6: public class Test Grade. Line 7: left brace. Line 8, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 9, indented once: left brace. Line 10, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 11: blank. Line 12, indented twice: System dot out dot print l n, left parentheses, double quotes, Enter your test grade, right parentheses, double quotes, right parentheses, semicolon. Line 13, indented twice: int grade, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 14: blank. Line 15, indented twice: System dot out dot print, left parentheses, double quotes, Enter your extra credit, right angled bracket, double quotes, right parentheses, semicolon. Line 16, indented twice: int extra Credit, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 17: blank. Line 18, indented twice: if, left parentheses, extra Credit greater than 0, right parentheses. Line 19, indented thrice: grade, plus, equals, extra Credit, semicolon. Line 20: blank. Line 21, indented twice: System dot out dot print l n, left parentheses, double quotes, Your final test grade is, double quotes. Line 22, indented multiple times: plus, grade, right parentheses, semicolon. Line 23, indented once: right brace. Line 24: right brace.

Back to Example

Program code. The code contains the following keywords: if, System, out, print l n. Line 1: if, left parentheses, grade, right angled bracket, equals sign, 60, right parentheses, semicolon. 2 forward slashes. incorrect to place semicolon here. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, You passed, double quotes, right parentheses, semicolon.

Back to Code

System dot out dot print l n, left parentheses, double quotes, You passed, double quotes, right parentheses, semicolon.

Back to Code

The patterns is as follows. Line 1: if, left parentheses, condition, right parentheses. Line 2: left brace. Line 3, indented once: true block. Line 4: right brace. Line 5: else.

Line 6: left brace. Line 7, indented once: false block. Line 8: right brace. Line 9: next statement.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, int, if, else. Line 1: forward slash, asterisk, Using if, forward slash, else. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class Passing Grade. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10: left brace. Line 11, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print, left parentheses, double quotes, Enter a grade, right angled bracket, double quotes, right parentheses, semicolon. Line 14, indented twice: int grade, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 15: blank. Line 16, indented twice: String message, semicolon. Line 17, indented twice: if, left parentheses, grade greater than or equal to 60, right parentheses. Line 18, indented thrice: message, equals, double quotes, You passed, double quotes, semicolon. Line 19, indented twice: else. Line 20, indented thrice: message, equals, double quotes, You failed, double quotes, semicolon. Line 21: blank. Line 22, indented twice: System dot out dot print l n, left parentheses, message, right parentheses, semicolon. Line 23, indented once: right brace. Line 24: right brace.

Back to Example

Line 1: if, left parentheses, grade greater than or equal to 60, right parentheses. Line 2, indented once: message, equals, double quotes, You passed, double quotes, semcolon. Line 3: blank. Line 4: if, left parentheses, grade less than 60, right parentheses. Line 5, indented once: message, equals, double quotes, You failed, double quotes, semicolon.

Back to Code

Program code. The code contains the following keywords: if, String, else, System, out, print l n. Line 1: if, left parentheses, grade, right angled bracket, equals sign, 60, right parentheses. Line 2: left brace. Line 3, indented once: String message equals, double quotes, You passed, double quotes, semicolon. Line 4: right brace. Line 5: else. Line 6, indented once: message equals double quotes, You failed, double quotes, semicolon. Line 7: blank. Line 8: System dot out dot print l n, left parentheses, message, right parentheses, semicolon.

Back to Code

The pattern is as follows. Line 1: if, left parentheses, condition 1, right parentheses. Line 2: left brace. Line 3, indented once: true block for condition 1. Line 4: right brace. Line 5: else if, left parentheses, condition 2, right parentheses. Line 6: left brace. Line 7, indented once: true block for condition 2. Line 8: right brace. Line 9: dot, dot, dot. Line 10: else if, left parentheses, condition n, right parentheses. Line 11: left brace. Line 12, indented once: true block for condition n. Line 13: right brace. Line 14: else. Line 15: left brace. Line 16, indented once: false block for all conditions being false. Line 17: right brace. Line 18: next statement.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, char, int, if, else. Line 1: forward slash, asterisk. A program to translate a numeric grade into a letter grade. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class Letter Grade. Line 8: left brace. Line 9, indented once: pubic static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: char letter Grade, semicolon. Line 14: blank. Line 15, indented twice: System dot out dot print, left parentheses, double quotes, Enter your test grade, colon, double quotes, right parentheses, semicolon Line 16, indented twice: int grade, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 17: blank. Line 18, indented twice: if, left parentheses, grade, greater than or equal to 90, right parentheses. Line 19, indented thrice: letter Grade, equals, single quote, uppercase a, single quote, semicolon. Line 20: blank. Line 21, indented twice: else if, left parentheses, grade greater than or equal to 80, right parentheses. Line 22, indented thrice: letter Grade, equals, single quote, uppercase b, single quote, semicolon. Line 23: blank. Line 24, indented twice: else if, left parentheses, grade greater than or equal to 70, right parentheses. Line 25, indented thrice: letter Grade, equals, single quote, uppercase c, single quote, semicolon. Line 26: blank. Line 27, indented twice: else if, left parentheses, grade greater than or equal to 60, right parentheses. Line 28, indented thrice: letter Grade, equals, single quote, uppercase d, single quote, semicolon. Line 29: blank. Line 30, indented twice: else, 2 forward slashes, grade fits none of the conditions. Line 31, indented thrice: letter Grade, equals, single quote, uppercase f, single quote, semicolon. Line 32: blank. Line 33, indented twice: System dot out dot print l n, left parentheses, double quotes, Your test grade of, double quotes, plus, grade. Line 34, indented multiple times: plus, double quotes, is a letter grade of, double quotes, plus, letter Grade, right parentheses, semicolon. Line 35, indented once: right brace. Line 36: right brace.

Back to Example

if, left parentheses, grade, right angled bracket, equals sign, 80, right parentheses.

Back to Code

if, left parentheses, grade, right angled bracket, equals sign, 80, 2 ampersand signs, grade, left angled bracket, 90, right parentheses.

Back to Code

Line 1: read number 1. Line 2: read number 2. Line 3: read number 3. Line 4: blank. Line 5: if number 1 is less than number 2. Line 6, indented once: smallest is number 1. Line 7: else. Line 8, indented once: smallest is number 2. Line 9: if number 3 is less than smallest. Line 10, indented once: smallest is number 3.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, int, new, if, else. Line 1: forward slash, asterisk, Find the smallest of three integers. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class Find Smallest. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: int smallest, semicolon. Line 12, indented twice: int num 1, comma, num 2, comma, num 3, semicolon. Line 13: blank. Line 14, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 15: blank. Line 16, indented twice: System dot out dot print, left parentheses, double quotes, Enter the first integer, colon, double quotes, right parentheses, semicolon. Line 17, indented twice: num 1, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 18, indented twice: System dot out dot print, left parentheses, double quotes, Enter the second integer, colon, double quotes, right parentheses, semicolon. Line 19, indented twice: num 2, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 20, indented twice: System dot out dot print, left parentheses, double quotes, Enter the third integer, colon, double quotes, right parentheses, semicolon. Line 21, indented twice: num 3, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 22: blank. Line 23, indented twice: if, left parentheses, num 1 less than num 2, right parentheses. Line 24, indented thrice: smallest, equals, num 1, semicolon. Line 25, indented twice: else. Line 26, indented thrice: smallest, equals, num 2, semicolon. Line 27: blank. Line 28, indented twice: if, left parentheses, num 3 less than smallest, right parentheses. Line 29, indented thrice: smallest, equals, num 3, semicolon. Line

30: blank. Line 31, indented twice: System dot out dot print l n, left parentheses, double quotes, The smallest is, double quotes, plus, smallest, right parentheses, semicolon. Line 32, indented once: right brace. Line 33: right brace.

Back to Example

Program code. The code contains the following keywords: if, else, System, out, print l n. Line 1: if, left parentheses, x, 2 equals sign, 2, right parentheses. Line 2, indented once: if, left parentheses, y, 2 equals sign, x, right parentheses. Line 3, indented twice: System dot out dot print l n, left parentheses, double quotes, x and y equal 2, double quotes, right parentheses, semicolon. Line 4, indented once: else. Line 5, indented twice: System dot out dot print l n, left parentheses, double quotes, x equals 2, comma, but y does not, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: if, else, System, out, print l n. Line 1: left brace. Line 2, indented once: if, left parentheses, y, 2 equals sign, x, right parentheses. Line 3, indented twice: System dot out dot print l n, left parentheses, double quotes, x and y equals 2, double quotes, right parentheses, semicolon. Line 4: right brace. Line 5: else. Line 6, indented once: System dot out dot print l n, left parentheses, double quotes, x does not equal 2, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: if, else, System, out, print l n.
Line 1: if, left parentheses, x, 2 equals sign, 2, right parentheses.
Line 2, indented once: if, left parentheses, y, 2 equals sign, x, right parentheses.
Line 3, indented twice: System dot out dot print l n, left parentheses, double quotes, x and y equal 2, double quotes, right parentheses, semicolon.
Line 4: blank.
Line 5, indented once: else. 2 forward slashes, matches y, 2 equals sign, x.
Line 6, indented twice: System dot out dot print l n, left parentheses, double quotes, y does not equal 2, double quotes, right parentheses, semicolon.
Line 7: blank.
Line 8: else. 2 forward slashes, matches x, 2 equals sign, 2.
Line 9, indented once: System dot out dot print l n, left parentheses, double quotes, x does not equals 2, double quotes, right parentheses, semicolon.
Line 10: blank.
Line 11: else. 2 forward slashes, no matching if, exclamation mark.
Line 12, indented once: System dot out dot print l n, left

parentheses, double quotes, x and y are not equal, double quotes, right parentheses, semicolon.

Back to Code

Line 1: generate a secret random number between 1 and 10. Line 2: prompt the user for a guess. Line 3: if guess is not between 1 and 10. Line 4, indented once: print message. Line 5: else. Line 6, indented once: if guess equals the secret number. Line 7, indented twice: print congratulations. Line 8, indented once: else. Line 9, indented twice: print the secret number. Line 10, indented twice: if guess is not within 3 numbers. Line 11, indented thrice: print, double quotes, You missed it by a mile, exclamation mark, double quotes. Line 12, indented twice: else. Line 13, indented thrice: print, double quotes, You were close, period, double quotes. Line 14, indented twice: print, double quotes, Better luck next time, period, double quotes.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, int, if, else. Line 1: forward slash, asterisk, Guess a number between 1 and 10. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java dot util dot Random, semicolon. Line 6: import java dot util dot Scanner, semicolon. Line 7: blank. Line 8: public class Guess A Number. Line 9: left brace.

Line 10, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 11, indented once: left brace. Line 12, indented twice: Random random, equals, new Random, left parentheses, right parentheses, semicolon. Line 13, indented twice: int secret Number, equals, random dot next Int, left parentheses, 10, right parentheses, plus, 1, semicolon. Line 14: blank. Line 15, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 16: blank. Line 17, indented twice: System dot out dot print, left parentheses, double quotes, I'm thinking of a number, double quotes. Line 18, indented multiple times: plus, double quotes, between 1 and 10. What is your guess, question mark, double quotes, right parentheses, semicolon. Line 19, indented twice: int guess, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 20: blank. Line 21, indented twice: if, left parentheses, guess less than 1, 2 pipes, guess greater than 10, right parentheses. Line 22, indented twice: left brace. Line 23, indented thrice: System dot out dot print l n, left parentheses, double quotes, Well, if you're not going to try, comma, double quotes. Line 24, indented multiple times: plus, double quotes, I'm not playing. double quotes, right parentheses, semicolon. Line 25, indented twice: right brace. Line 26, indented twice: else. Line 27, indented twice: left brace. Line 28, indented thrice: if, left parentheses, guess, 2 equals sign, secret Number, right parentheses. Line 29, indented 4 times: System dot out dot print l n, left parentheses, double quotes, Hoorah. You win, exclamation mark, double quotes, right parentheses, semicolon. Line 30, indented thrice: else. Line 31, indented thrice: left brace. Line 32, indented 4 times: System dot out dot print l n, left parentheses, double quotes, The number was, double quotes, plus, secret Number, right parentheses, semicolon. Line 33: blank. Line 34, indented 4 times: if, left parentheses, Math dot a b s, left parentheses, guess minus secret Number, right parentheses, greater than 3, right parentheses. Line 35, indented 5 times: System dot out dot print l n, left parentheses, double quotes, You missed it by a mile, exclamation mark, double quotes, right parentheses, semicolon. Line 36, indented 4 times: else. Line 37, indented 5 times: System dot out dot print l n, left parentheses, double quotes, You were close, period, double quotes, right parentheses, semicolon. Line 38: blank. Line 39, indented 4 times: System dot out dot print l n, left parentheses, double quotes, Better luck next time, period, double quotes, right parentheses, semicolon. Line 40, indented thrice: right brace. Line 41, indented twice: right brace. Line 42: indented once: right brace. Line 43: right brace.

Back to Example

Program code. The code contains the following keywords: int, if, else. Line 1: System dot out dot print t, left parentheses, double quotes, Enter an integer, right angled bracket, double quotes, right parentheses, semicolon. Line 2: int x equals scan dot next Int, left parentheses, right parentheses, semicolon. Line 3: if, left parentheses, x, right angled bracket, 0, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, x plus, double quotes, is positive, double quotes, right parentheses, semicolon. Line 5: else. Line 6, indented once: System dot out dot print l n, left parentheses, x plus double quotes, is negative, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: int, if, else. Line 1: System dot out dot print t, left parentheses, double quotes, Enter an integer, right angled bracket, double quotes, right parentheses, semicolon. Line 2: int x equals scan dot next Int, left parentheses, right parentheses, semicolon. Line 3: if, left parentheses, x, right angled bracket, 0, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, x plus, double quotes, is positive, double quotes, right parentheses, semicolon. Line 5: else if, left parentheses, x left angled bracket 0, right parentheses. Line 6, indented once: System dot out dot print l n, left parentheses, x plus double quotes, is negative, double quotes, right parentheses, semicolon. Line 7: else. Line 8, indented once: System dot out dot print l n, left parentheses, double quotes, The integer is 0, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, void, int, String. Line 1: public void work With If Else, left parentheses, int score, right parentheses. Line 2: left brace. Line 3, indented once: String result, equals, double quotes, 3 question marks, double quotes, semicolon. Line 4, indented once: 2 forward slashes, 5 asterisks, Student code starts here. Line 5, indented once: 2 forward slashes. If score is greater than 72, comma, assign, double quotes, over par, double quotes, to result. Line 6, indented once: If score is equal to 72, comma, assign, double quotes, par, double quotes, to result. Line 7, indented once: 2 forward slashes. If score is less than 72, comma, assign, double quotes, below par, double quotes, to result. Lines 8, 9, and 10: blank. Line 11, indented once: 2 forward slashes. Line 12, indented once: 2 forward slashes. Student code ends here. Line 13, indented once: 2 forward slashes. Line 14: blank. Line 15, indented once: animate, left parentheses, score, comma, result, right parentheses, semicolon. Line 16: right brace.

Line 38, indented twice: System dot out dot print l n, left parentheses, double quotes, back slash, n, p i F, equals, double quotes, plus, p i F, right parentheses, semicolon. Line 39, indented twice: System dot out dot print l n, left parentheses, double quotes, p i D, equals, double quotes, plus, p i D, right parentheses, semicolon. Line 40, indented twice: if, left parentheses, Math dot a b s, left parentheses, p i F minus p i D, right parentheses, less than, THRESHOLD, right parentheses. Line 41, indented thrice: System dot out dot print l n, left parentheses, double quotes, p i F and p i D are considered equal, double quotes, right parentheses, semicolon. Line 42, indented twice: else. Line 43, indented thrice: System dot out dot print l n, left parentheses, double quotes, p i F and p i are not equal, double quotes, right parentheses, semicolon. Line 44, indented once: right brace. Line 45: right brace.

Back to Example

The Big Decimal Class Constructor Summary is as follows. Big Decimal, left parentheses, String d d d, right

parentheses, creates a Big Decimal object equivalent to the decimal number expressed as a String. The second table is titled Big Decimal Class Method Summary and it has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.
Row 1. Return value: Big Decimal. Method name and argument list: add, left parentheses, Big Decimal n u m, right parentheses, returns a Big Decimal object equal to the current Big Decimal object plus num.
Row 2. Return value: Big Decimal. Method name and argument list: subtract, left parentheses, Big Decimal num, right parentheses, returns a Big Decimal object equal to the current Big Decimal object minus num.
Row 3. Return value: Big Decimal. Method name and argument list: multiply, left parentheses, Big Decimal num, right parentheses, returns a Big Decimal object equal to the current Big Decimal object times num.
Row 4. Return value: Big Decimal. Method name and argument list: divide, left parentheses, Big Decimal num, right parentheses, returns a Big Decimal object equal to the current Big Decimal object divided by num.
Row 5. Return value: int. Method name and argument list: compare To, left parentheses, Big Decimal num, right parentheses, returns 0 if the current Big Decimal object is equal to num; negative 1 if the current Big Decimal object is less than num; and 1 if the current Big Decimal object is greater than num.

Back to Table

Program code. The code contains the following keywords: import, public, class, static, void, if, else. Line 1: forward slash, asterisk, Using Big Decimal to compute precise decimal numbers. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java dot math dot Big Decimal, semicolon. Line 6: blank. Line 7: public class Using Big Decimal. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: Big Decimal d 1, equals, new Big Decimal, left parentheses, double quotes, 0.0, double quotes, right parentheses, semicolon. Line 12, indented twice: Big Decimal point One, equals, new Big Decimal, left parentheses, double quotes, 0.1, double quotes, right parentheses, semicolon. Line 13: blank. Line 14, indented twice: 2 forward slashes, Compute 11, asterisk, decimal point, 1, two ways. Line 15, indented twice: 2 forward slashes, add, decimal point, 1, to d 1, eleven times. Line 16, indented twice: d 1, equals, d 1, dot, add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 1. Line 17, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 2. Line 18, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 3. Line 19, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 4. Line 20, indented twice: d 1, equals, d 1, dot, add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 5. Line 21, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 6. Line 22, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 7. Line 23, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 8. Line 24, indented twice: d 1, equals, d 1, dot, add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 9. Line 25, indented twice: d 1, equals, d 1 dot add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 10. Line 26, indented twice: d 1, equals, d 1, dot, add, left parentheses, point One, right parentheses, semicolon. 2 forward slashes, 11. Line 27: blank. Line 28, indented twice: 2 forward slashes, multiply, decimal point 1, asterisk, 11. Line 29, indented twice: Big Decimal, d 2, equals, new Big Decimal, left parentheses, double quotes, 0.1, double quotes, right parentheses, semicolon. Line 30, indented twice: Big Decimal, eleven, equals, new, Big Decimal, left parentheses, double quotes, 11, double quotes, right parentheses, semicolon. Line 31, indented twice: d 2, equals, d 2, dot, multiply, left parentheses, eleven, right parentheses, semicolon. Line 32: blank. Line 33, indented twice: System dot out dot print l n, left parentheses, double quotes, d 1, equals, double quotes, plus, d 1, right parentheses, semicolon. Line 34, indented twice: System dot out dot print l n, left parentheses, double quotes, d 2, equals, double quotes, plus, d 2, right parentheses, semicolon. Line 35, indented twice: if, left parentheses, d 1 dot compare To, left parentheses, d 2, right parentheses, 2 equals sign, 0, right parentheses. Line 36, indented thrice: System dot out dot print l n, left parentheses, double quotes, d 1 and d 2 are equal, double quotes, right parentheses, semicolon. Line 37, indented twice: else. Line 38, indented thrice: System dot out dot print l n, left parentheses, double quotes, d 1 and d 2 are not equal, double quotes, right parentheses, semicolon. Line 39, indented once: right brace. Line 40: right brace.

Back to Example

public boolean equals, left parentheses, Object o b, right parentheses.

Back to Code

Program code. The code contains the following keywords: public, class, static, void, new, if, else. Line 1: Forward slash, asterisk, Comparing Object References and data. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: public class Comparing Objects. Line 5: left brace. Line 6, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 7, indented once: left brace. Line 8, indented twice: String s 1, equals, new String, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 9, indented twice: String s 2, equals, new String, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 10: blank. Line 11, indented twice: if, left parentheses, s 1, 2 equals sign, s 2, right parentheses. Line 12, indented thrice: System dot out dot print l n, left parentheses, double quotes, Using, 2 equals sign, comma, s 1 and s 2 are equal, double quotes, right parentheses, semicolon. Line 13, indented twice: else. Line 14, indented thrice: System dot out dot print l n, left parentheses, double quotes, Using, 2 equals sign, comma, s 1 and s 2 are different, double quotes, right parentheses, semicolon. Line 15: blank. Line 16, indented twice: if, left parentheses, s 1 dot equals, left parentheses, s 2, right parentheses, right parentheses. Line 17, indented thrice: System dot out dot print l n, left parentheses, double quotes, Using equals, comma, s 1 and s 2 are equal, double quotes, right parentheses, semicolon. Line 18, indented twice: else. Line 19, indented thrice: System dot out dot print l n, left parentheses, double quotes, Using equals, comma, s 1 and s 2 are different, double quotes, right parentheses, semicolon. Line 20, indented once: right brace. Line 21: right brace.

Back to Example

The table is titled, String Methods for Comparing String

Values. The table has 2 columns labelled Return value and Method name and argument list. The row entries are as follows.
Row 1. Return value: boolean. Method name and argument list: equals, left parentheses, String s t r, right parentheses.
Row 2. Return value: boolean. Method name and argument list: equals Ignore Case, left parentheses, String s t r, right parentheses, compares the value of two Strings, treating upper and lowercase characters as equal. Returns true if the Strings are equal; false otherwise.
Row 3. Return value: int. Method name and argument list: compare To, left parentheses, String s t r, right parentheses, compares the value of the two Strings in lexicographic order. If the String object is less than the String argument, s t r, a negative integer is returned. If the String object is greater than the String argument, a positive number is returned; if the two Strings are equal, 0 is returned.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, String, if, else. Line 1: Forward slash, asterisk. Demonstration of the String comparison methods. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: blank. Line 5: public class Comparing Strings. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: String title 1, equals, double quotes, Green Pastures, double quotes, semicolon. Line 10, indented twice: String title 2, equals, double quotes, Green Pastures, roman numeral 2, double quotes, semicolon. Line 11, indented twice: String title 3, equals, double quotes, green pastures, double quotes, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print, left parentheses, double quotes, Using equals, colon, blank space, double quotes, right parentheses, semicolon. Line 14, indented twice: if, left parentheses, title 1 dot equals, left parentheses, title 3, right parentheses, right parentheses. Line 15, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, equals, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 16, indented twice: else. Line 17, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is not equal to, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 18: blank. Line 19, indented twice: System dot out dot print, left parentheses, double quotes, Using equals Ignore Case, colon, blank space, double quotes, right parentheses, semicolon. Line 20, indented twice: if, left parentheses, title 1 dot equals Ignore Case, left parentheses, title 3, right parentheses, right parentheses. Line 21, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, equals, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 22, indenteed twice: else. Line 23, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is not equal to, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 24: blank. Line 25, indented twice: System dot out dot print, left parentheses, double quotes, Using compare To, colon, blank space, double quotes, right parentheses, semicolon. Line 26, indented twice: if, left parentheses, title 1 dot compare To, left parentheses, title 3, right parentheses, greater than 0, right parentheses. Line 27, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is greater than, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 28, indented twice: else if, left parentheses, title 1 dot compare To, left parentheses, title 3, right parentheses, less than 0, right parentheses. Line 29, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is less than, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 30, indented twice: else. Line 31, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is equal to, blank space, double quotes, plus, title 3, right parentheses, semicolon. Line 32: blank. Line 33, indented twice: System dot out dot print, left parentheses, double quotes, Using compare To, colon, blank space, double quotes, right parentheses, semicolon. Line 34, indented twice: if, left parentheses, title 1 dot compare To, left parentheses, title 2, right parentheses, greater than 0, right parentheses. Line 35, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is greater than, blank space, double quotes, plus, title 2, right parentheses, semicolon. Line 36, indented twice: else if, left parentheses, title 1 dot compare To, left parentheses, title 2, right parentheses, less than 0, right parentheses. Line 37, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, blank space, is less than, blank space, double quotes, plus, title 2, right parentheses, semicolon. Line 38, indented twice: else. Line 39, indented thrice: System dot out dot print l n, left parentheses, title 1, plus, double quotes, plus, is equal to, blank space, double quotes, plus, title 2, right parentheses, semicolon. Line 42, indented once: right brace. Line 41: right brace.

Back to Example

The syntax is as follows: left parentheses, condition, question mark, expression 1, colon, expression 2, right parentheses.

Back to Code

The conditional statement is as follows. variable equals, left parentheses, condition, question mark, expression 1, colon, expression 2, right parentheses, semicolon.

Back to Code

The equivalent if else statement is as follows. Line 1: if, left parentheses, condition, right parentheses. Line 2, indented once: variable equals expression 1, semicolon. Line 3: else. Line 4, indented once: variable equals expression 2, semicolon.

Back to Code

Program code. The code contains the keywords if and else. Line 1: if, left parentheses, number percentage sign 2, 2 equals sign, 0, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, number plus double quotes, blank space, is even, period, double quotes, right parentheses, semicolon. Line 3: else. Line 4 indented once: System dot out dot print l n, left parentheses, number plus, double quotes, blank space, is odd, period, double quotes, right parentheses.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, int. Line 1: Forward slash, asterisk. Using the conditional operator. Line 2, indented twice: Anderson, comma, Franceschi. Line 3: asterisk. Forward slash. Line 4: blank. Line 5: import java dot util dot Scanner, semicolon. Line 6: blank. Line 7: public class Odd Or Even. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line

11, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 12: blank. Line 13, indented twice: System dot out dot print, left parentheses, double quotes, Enter an integer, right angled bracket, double quotes, right parentheses, semicolon. Line 14, indented twice: int number, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 15: blank. Line 16, indented twice: String outcome, equals, left parentheses, number, percentage sign, 2, 2 equals sign, 0, question mark, double quotes, even, period, double quotes, colon, double quotes, odd, period, double quotes, right parentheses, semicolon. Line 17: blank. Line 18, indented twice: System dot out dot print l n, left parentheses, number, plus, double quotes, blank space, is, double quotes, plus, outcome, right parentheses, semicolon. Line 19: blank. Line 20, indented once: right brace. Line 21: right brace.

Back to Example

The table has 3 columns labeled Operation Hierarchy, Order of Same Statement Evaluation, and Operation. Row 1. Operation Hierarchy: left parentheses, right parentheses. Order of Same Statement Evaluation: left to right. Operation: parentheses for explicit grouping. Row 2. Operation Hierarchy: plus plus, minus minus. Order of Same Statement Evaluation: right to left. Operation: shortcut postincrement. Row 3. Operation Hierarchy: plus plus, minus minus, exclamation mark. Order of Same Statement Evaluation: right to left. Operation: shortcut preincrement, logical unary NOT. Row 4. Operation Hierarchy: asterisk, forward slash, percentage sign. Order of Same Statement Evaluation: left to right. Operation: multiplication, division, modulus. Row 5. Operation Hierarchy: plus, minus. Order of Same Statement Evaluation: left to right. Operation: addition or String concatenation, subtraction. Row 6. Operation Hierarchy: less than, less than or equal to, greater than, greater than or equal to. Order of Same Statement Evaluation: left to right. Operation: relational operators: less than, less than or equal to, greater than, greater than or equal to. Row 7. Operation Hierarchy: 2 equals sign, exclamation mark equals. Order of Same Statement Evaluation: left to right. Operation: equality operators: equal to and not equal to. Row 8. Operation Hierarchy: 2 ampersand signs. Order of Same Statement Evaluation: left to right. Operation: logical AND. Row 9. Operation Hierarchy: 2 pipes. Order of Same Statement Evaluation: left to right. Operation: logical OR. Row 10. Operation Hierarchy: question mark, colon. Order of Same Statement Evaluation: left to right. Operation: conditional operator. Row 11. Operation Hierarchy: equals, plus equals, minus equals, asterisk equals, forward slash equals, percentage sign equals. Order of Same Statement Evaluation: right to left. Operation: assignment operator and shortcut assignment operators.

Back to Table

Program code. The code contains the keywords switch, case and default. Line 1: switch, left parentheses, expression, right parentheses. Line 2: left brace. Line 3, indented once: case constant 1 A, comma, constant 1 B, comma, dot, dot, dot, hyphen, right angled bracket, statement or block, semicolon. Line 4, indented once: case constant 2 A, comma, constant 2 B, comma, dot, dot, dot, hyphen, right angled bracket, statement or block, semicolon. Line 5: dot, dot, dot. Line 6, indented once: default, hyphen, right angled bracket, statement or block, semicolon. 2 forward slashes. optional, left parentheses, but often needed, right parentheses. Line 7: right brace.

Back to Code

Program code. The code contains the keywords switch, case, and default. Line 1: switch, left parentheses, letter Grade, right parentheses. Line 2: left brace. Line 3, indented once: case, single quote, uppercase a, single quote, hyphen, right angled bracket, System dot out dot print l n, left parentheses, double quotes, 90 hyphen 100, double quotes, right parentheses, semicolon. Line 4, indented once: case, single quote, uppecase b, single quote, hyphen, right angled bracket, System dot out dot print l n, left parentheses, double quotes, 80 hyphen 89, double quotes, right parentheses, semicolon. Line 5, indented once: default, hyphen, right angled bracket, System dot out dot print l n, left parentheses, double quotes, 0 hyphen 79, double quotes, right parentheses, semicolon. Line 6: right brace.

Back to Code

Program code. The code contains the keywords if, and else. Line 1: if, left parentheses, letter Grade, 2 equals sign, single quote, uppercase a, single quote, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, 90 hyphen 100, double quotes, right parentheses, semicolon. Line 3: else if, left parentheses, letter Grade, 2 equals sign, single quotes, uppercase b, single quote, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, double quotes, 80 hyphen 89, double quotes, right parentheses, semicolon. Line 5: else. Line 6, indented once: System dot out dot print l n, left parentheses, double quotes, 0 hyphen 79, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the keywords switch, case, break, and default. Line 1: switch, left parentheses, letter Grade, right parentheses. Line 2: left brace. Line 3, indented once: case, single quote, uppercase a, single quote, colon. Line 4, indented twice: System dot out dot print l n, left parentheses, double quotes, 90 hyphen 100, double quotes, right parentheses, semicolon. Line 5, indented twice: break, semicolon. Line 6, indented once: case, single quote, uppercase b, single quote, colon. Line 7, indented twice: System dot out dot print l n, left parentheses, double quotes, 80 hyphen 89, double quotes, right parentheses, semicolon. Line 8, indented twice: break, semicolon. Line 9, indented once: default, colon. Line 10, indented twice: System dot out dot print l n, left parentheses, double quotes, 0 hyphen 79, double quotes, right parentheses, semicolon. Line 11: right brace.

Back to Code

Program code. The code contains the keywords switch, case, yield and default. Line 1: data type identifier equals switch, left parentheses, expression, right parentheses. Line 2: left brace. Line 3, indented once: case constant 1 A, comma, constant 1 B, comma, dot, dot, dot, hyphen, right angled bracket, expression or block with yield, semicolon. Line 4, indented once: case constant 2 A, comma, constant 2 B, comma, dot, dot, dot, hyphen, right angled bracket, expression or block with yield, semicolon. Line 5: dot, dot, dot. Line 6, indented once: 2 forward slashes, optional default, left parentheses, but often needed, right parentheses. Line 7, indented once: default, hyphen, right angled bracket, expression or block with yield, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, new, double, String, swtich, case, if, else, yield, default. Line 1: Forward slash, asterisk. A simple calculator. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java dot text dot Decimal Format, semicolon. Line 6: import java dot util dot Scanner, semicolon. Line 7: blank. Line 8: public class Calculator. Line 9: left brace. Line 10, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 11, indented once: left brace. Line 12, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 13: blank. Line 14, indented twice: 2 forward slashes. set up the output format of the result. Line 15, indented twice: Decimal Format two Decimals, equals, new Decimal Format, left parentheses, double quotes, hash, comma, hash, hash, hash, decimal point, hash, hash, double quotes, right parentheses, semicolon. Line 16: blank. Line 17, indented twice: 2 forward slashes. print a welcome message. Line 18, indented twice: System dot out dot print l n, left parentheses, double quotes, Welcome to the Calculator, double quotes, right parentheses, semicolon. Line 19: blank. Line 20, indented twice: 2 forward slashes, define and print a menu, comma, then prompt for the operation. Line 21, indented twice: String menu, equals, 3 double quotes. Line 22, indented thrice: Operations are, colon. Line 23, indented thrice: backslash t, ADD, or, plus, for addition. Line 24, indented thrice: backslash t, SUBTRACT or minus for subtraction. Line 25, indented thrice: backslash t, MULTIPLY or asterisk for multiplication. Line 26, indented thrice: backslash t, DIVIDE of forward slash for division, 3 double quotes, semicolon. Line 27, indented twice: System dot out dot print l n, left parentheses, menu, right parentheses, semicolon. Line 28, indented twice: System dot out dot print, left parentheses, double quotes, Enter your operator, colon, blank space, double quotes, right parentheses, semicolon. Line 29, indented twice: String operation, equals, scan dot next, left parentheses, right parentheses, semicolon. Line 30, indented twice: operation, equals, operation dot to Upper Case, left parentheses, right parentheses, semicolon. Line 31: blank. Line 32, indented twice: 2 forward slashes, read the two operands. Line 33, indented twice: System dot out dot print, left parentheses, double quotes, Enter the first operand, colon, blank space, double quotes, right parentheses, semicolon. Line 34, indented twice: double f p 1, equals, scan dot next Double, left parentheses, right parentheses, semicolon. Line 30, indented twice: operation, equals, operation dot to Upper Case, left parentheses, right parentheses, semicolon. Line 31: blank. Line 32, indented twice: 2 forward slashes. read the two operands. Line 33, indented twice: System dot out dot print, left parentheses, double quotes, Enter the first operand, colon, blank space, double quotes, right parentheses, semicolon. Line 34, indented twice: double f p 1, equals, scan dot next Double, left parentheses, right parentheses, semicolon. Line 35, indented twice: System dot out dot print, left parentheses, double quotes, Enter the second operand, colon, blank space, double quotes, right parentheses, semicolon. Line 36, indented twice:

double f p 2, equals, scan dot next Double, left parentheses, right parentheses, semicolon. Line 37: blank. Line 38, indented twice: 2 forward slashes. perform the operation. Line 39, indented twice: String result, equals, switch, left parentheses, operation, right parentheses. Line 40, indented twice: left brace. Line 41, indented thrice: case, double quotes, ADD, double quotes, comma, double quotes, plus, double quotes, hyphen, right angled bracket, two Decimals dot format, left parentheses, f p 1, plus, f p 2, right parentheses, semicolon. Line 42, indented thrice: case, double quotes, SUBTRACT, double quotes, comma, double quotes, minus sign, double quotes, hyphen, right angled bracket, two Decimals dot format, left parentheses, f p 1 minus f p 2, right parentheses, semicolon. Line 43, indented thrice: case double quotes, MULTIPLY, double quotes, comma, double quotes, asterisk, double quotes, hyphen, right angled bracket, two Decimals dot format, left parentheses, f p 1 asterisk f p 2, right parentheses, semicolon. Line 44, indented thrice: case, double quotes, DIVIDE, double quotes, comma, double quotes, forward slash, double quotes, hyphen, right angled bracket. Line 45, indented thrice: left brace. Line 46, indented 4 times: if, left parentheses, f p 2, 2 equals sign, 0.0, right parentheses. Line 47, indented 5 times: yield, double quotes, Dividing by 0 is not allowed, double quotes, semicolon. Line 48, indented 4 times: else. Line 49, indented 5 times: yield, two Decimals dot format, left parentheses, f p 1, forward slash, f p 2, right parentheses, semicolon. Line 50, indented thrice: right brace. Line 51, indented thrice: default, hyphen, right angled bracket, double quotes, Invalid operation, double quotes, semicolon. Line 52, indented twice: right brace, semicolon. Line 53: blank. Line 54, indented twice: 2 forward slashes. output the result of the operation. Line 55, indented twice: System dot out dot print l n, left parentheses, double quotes, The result is, colon, blank space, double quotes, plus, result, right parentheses, semicolon. Line 56, indented once: right bace. Line 57: right brace.

Back to Example

Program code. The code contains the following keywords: import, public, class, extends, at symbol Override, void, final, int, switch, case, default, static, void. Line 1: Forward slash, asterisk. Drawing a smiley face. Line 2, indented once: Anderson, comma, Franceschi. Line 3: asterisk, forward slash. Line 4: blank. Line 5: import java f x dot application dot Application, semicolon. Line 6: import java f x dot scene dot canvas dot Graphics Context, semicolon. Line 7: import java f x dot scene dot paint dot Color, semicolon. Line 8: import java f x dot scene dot shape dot Arc Type, semicolon. Line 9: import java f x dot stage dot Stage, semicolon. Line 10: blank. Line 11: import java dot util dot Scanner, semicolon. Line 12: blank. Line 13: public class Smiley Face Draw extends Application. Line 14: left brace. Line 15, indented once: at symbol, Override. Line 16, indented once: public void start, left parentheses, Stage stage, right parentheses. Line 17, indented once: left brace. Line 18, indented twice: 2 forward slashes, set up window title and size. Line 19, indented twice: Graphics Context g c, equals, J I Graphics Utility dot set Up Graphics, left parentheses. Line 20, indented multiple times: stage, comma, double quotes, Draw a Smiley Face, double quotes, comma, 400, comma, 400, right parentheses, semicolon. Line 21: blank. Line 22, indented twice: final int, uppercase x, equals, 100, comma, uppercase y, equals, 100, comma, RADIUS, equals, 100, semicolon. Line 23: blank. Line 24, indented twice: 2 forward slashes. ask the user for a rating. Line 25, indented twice: Scanner scan, equals, new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 26, indented twice: System dot out dot print, left parentheses, double quotes, Enter a rating, left parentheses, 1 to 5, right parentheses, right angled bracket, double quotes, right parentheses, semicolon. Line 27, indented twice: int rating, equals, scan dot next Int, left parentheses, right parentheses, semicolon. Line 28: blank. Line 29, indented twice: 2 forward slashes. Draw the face and the eyes. Line 30, indented twice: g c dot set Fill, left parentheses, Color dot YELLOW, right parentheses, semicolon. Line 31, indented twice: g c dot fill Oval, left parentheses, uppercase x, comma, uppercase y, comma, 2 asterisk RADIUS, comma, 2 asterisk RADIUS, right parentheses, semicolon. Line 32, indented twice: g c dot set Fill, left parentheses, Color dot BLACK, right parentheses, semicolon. Line 33, indented twice: g c dot fill Oval, left parentheses, uppercase x, plus, RADIUS, forward slash, 3, comma, uppercase y plus RADIUS, forward slash, 3, comma. Line 34, indented multiple times: RADIUS, forward slash, 3, comma, RADIUS, forward slash, 3, right parentheses, semicolon. Line 35, indented twice: g c dot fill Oval, left parentheses, uppercase x plus 4 asterisk RADIUS forward slash 3, comma, uppercase y plus RADIUS, forward slash, 3, comma. Line 36, indented multiple times: RADIUS, forward slash, 3, comma, RADIUS, forward slash, 3, right parentheses, semicolon. Line 37: blank. Line 38, indented twice: 2 forward slashes, Draw the smile. Line 39, indented twice: switch, left parentheses, rating, right parentheses. Line 40, indented twice: left brace. Line 41, indented thrice: case 1, comma, 2, hyphen, right angled bracket. Line 42, indented 4 times: g c dot stroke Arc, left parentheses, uppercase x plus RADIUS, forward slash, 2, comma, uppercase y, plus, RADIUS, comma. Line 43, indented multiple times: RADIUS, comma, RADIUS forward slash 2, comma, 0, comma, 180, comma, Arc Type dot OPEN, right parentheses, semicolon. Line 44, indented thrice: case 4, comma, 5, hyphen, right angled bracket. Line 45, indented 4 times: g c dot stroke Arc, left parentheses, uppercase x plus RADIUS forward slash 2, comma, uppercase y plus RADIUS, comma. Line 46, indented multiple times: RADIUS, comma, RADIUS, forward slash, 2, comma, 0, comma, negative 180, comma, Arc Type dot OPEN, right parentheses, semicolon. Line 47, indented thrice: default, hyphen, right angled bracket. Line 48, indented 4 times: g c dot stroke Line, left parentheses, uppercase x plus RADIUS forward slash 2, comma, uppercase y plus 4 asterisk RADIUS forward slash 3, comma. Line 49, indented multiple times: uppercase x plus 3 asterisk RADIUS forward slash 2, comma, uppercase y plus 4 asterisk RADIUS forward slash 3, right parentheses, semicolon. Line 50, indented twice: right brace. 2 forward slashes, end switch. Line 41, indented once: right brace. Line 52: blank. Line 53, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 54, indented once: left brace. Line 55, indented twice: launch, left parentheses, a r g s, right parentheses, semicolon. Line 56, indented once: right brace. Line 57: right brace.

Back to Example

Program code. The code contains the following keywords: public, void, int. Line 1: 2 forward slashes, 5 asterisks, 1 student writes this method. Line 2: public void work With Switch, left parentheses, int value, right parentheses. Line 3: left brace. Line 4, indented once: 2 forward slashes. Line 5, indented once: 2 forward slashes, Student code starts here. Line 6, indented once: 2 forward slashes. Line 7: blank. Line 8: blank. Line 9, indented once: 2 forward slashes. Line 10, indented once: 2 forward slashes, Student code ends here. Line 11, indented once: 2 forward slashes. Line 12: blank. Line 13: blank. Line 14:

right brace. Line 15: 2 forward slashes, end of work With Switch.

Back to Example

void animate, left parentheses, int case Constant, comma, int value, right parentheses.

Back to Code

animate, left parentheses, 2, comma, value, right parentheses, semicolon.

Back to Code

animate, left parentheses, negative 1, comma, value, right parentheses, semicolon.

Back to Code

Line 1: int a equals 3, semicolon. Line 2: int b equals 5, semicolon.

Back to Code

Line 1: boolean a equals true, semicolon. Line 2: boolean b equals true, semicolon. Line 3: boolean c equals false, semicolon.

Back to Code

Line 1: int a equals 3, semicolon. Line 2: int b equals 5, semicolon.

Back to Code

Line 1: boolean a equals true, semicolon. Line 2: System dot out dot print l n, left parentheses, a, right parentheses, semicolon.

Back to Code

Line 1: boolean a equals left parentheses, true, 2 ampersand signs, false, right parentheses, semicolon. Line 2: System dot out dot print l n, left parentheses, a, right parentheses, semicolon.

Back to Code

Line 1: if, left parentheses, left parentheses, true, 2 pipes, false, right parentheses, 2 ampersands, left parentheses, false, 2 pipes, true, right parentheses, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, Inside true block, double quotes, right parentheses, semicolon. Line 3: System dot out dot print l n, left parentheses, double quotes, End of sequence, double quotes, right parentheses, semicolon.

Back to Code

Line 1: if, left parentheses, 27 percentage sign 3, 2 equals sign, 0, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, 27 is divisible by 3, double quotes, right parentheses, semicolon. Line 3: else. Line 4, indented once: System dot out dot print l n, left parentheses, double quotes, 27 is not divisible by 3, double quotes, right parentheses, semicolon. Line 5: System dot out dot print l n, left parentheses, double quotes, End of sequence, double quotes, right parentheses, semicolon.

Back to Code

Line 1: String s equals double quotes, Hello, double quotes, semicolon. Line 2: if, left parentheses, s dot equals, left parentheses, double quotes, hello, double quotes, right parentheses, right parentheses. Line 3, indented once: System dot out dot print l n, left parentheses, double quots, String is hello, double quotes, right parentheses, semicolon. Line 4: else. Line 5, indented once: System dot out dot print l n, left parentheses, double quotes, String is not hello, double quotes, right parentheses, semicolon. Line 6: System dot out dot print l n, left parentheses, double quotes, End of sequence, double quotes, right parentheses, semicolon.

Back to Code

Line 1: int grade equals 77, semicolon. Line 2: if, left parentheses, grade greater than or equal to 90, right parentheses. Line 3, indented once: System dot out dot print l n, left parentheses, double quotes, uppercase a, double quotes, right parentheses, semicolon. Line 4: else if, left parentheses, grade greater than or equal to 80, right parentheses. Line 29, indented twice: System dot out dot print l n, left parentheses, double quotes, Sentinel value detected. Goodbye, double quotes, right parentheses, semicolon. Line 30, indented once: right brace. Line 31: right brace.

Back to Example

The title of the table is, Selected Methods of the Scanner Class. The syntax for the Scanner constructor is as follows: Scanner, left parentheses, File, blank space, file, right parentheses. The description below the syntax is as follows: creates a Scanner object and associates it with a file. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: boolean. Method name and argument list: has Next, left parentheses, right parentheses, returns true if there is another token in the input stream; false, otherwise. Row 2. Return value: byte. Method name and argument list: next Byte, left parentheses, right parentheses, returns the next input as a byte. Row 3. Return value: short. Method name and argument list: next Short, left parentheses, right parentheses, returns the next input as a short. Row 4. Return value: int. Method name and argument list: next Int, left parentheses, right parentheses, returns the next input as an int. Row 5. Return value: long. Method name and argument list: next Long, left parentheses, right parentheses, returns the next input as a long. Row 6. Return value: float. Method name and argument list: next Float, left parentheses, right parentheses, returns the next input as a float. Row 7. Return value: double. Method name and argument list: next Double, left parentheses, right parentheses, returns the next input as a double. Row 8. Return value: boolean. Method name and argument list: next Boolean, left parentheses, right parentheses, returns the next input as a boolean. Row 9. Return value: String. Method name and argument list: next, left parentheses, right parentheses, returns the next token in the input line as a String.

Back to Table

The title of the table is, A constructor for the File class. The syntax for the File class constructor is as follows: File, left parentheses, String path name, right parentheses, constructs a File object with the path name file name so that the file name is platform independent.

The title of the table is, Selected Input Stream Testing Methods of the Scanner Class. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: boolean. Method name and argument list: has Next, left parentheses, right parentheses, returns true if there is another token in the input stream; false, otherwise. Row 2. Return value: boolean. Method name and argument list: has Next Byte, left parentheses, right parentheses, returns true if the token in the input stream can be read as a byte; false, otherwise. Row 3. Return value: boolean. Method name and argument list: has Next Short, left parentheses, right parentheses, returns true if the token in the input stream can be read as a short; false, otherwise. Row 4. Return value: boolean. Method name and argument list: has Next Int, left parentheses, right parentheses, returns true if the token in the input stream can be read as an int; false, otherwise. Row 5. Return value: boolean. Method name and argument list: has Next Long, left parentheses, right parentheses, returns true if the token in the input stream can be read as a long; false, otherwise. Row 6. Return value: boolean. Method name and argument list: has Next Float, left parentheses, right parentheses, returns true if the token in the input stream can be read as a float; false, otherwise. Row 7. Return value: boolean. Method name and argument list: has Next Double, left parentheses, right parentheses, returns true if the token in the input stream can be read as a double; false, otherwise. Row 8. Return value: boolean. Method name and argument list: has Next Boolean, left parentheses, right parentheses, returns true if the token in the input stream can be read as a boolean; false, otherwise. Row 9. Return value: String. Method name and argument list: next Line, left parentheses, right parentheses, returns the remainder of the input line as a String.

The table has 2 columns labeled Return type, and Method name and argument list. The row entries are as follows. Row 1. Return type: int. Method name and argument list: compare To, left parentheses, Enum e O b j, right parentheses, compares two enum objects and returns a negative number if this object is less than the argument, a positive number if this object is greater than the argument, and 0 if the two objects are the same. Row 2. Return type: boolean. Method name and argument list: equals, left parentheses, Object e O b j, right parentheses, returns true if this object is equal to the argument e O b j, semicolon, returns false otherwise. Row 3. Return type: int. Method name and argument list: ordinal, left parentheses, right parentheses, returns the numeric value of the enum object; by default; the value of the first object in the list is 0, the value of the second object is 1, and so on. Row 4. Return type: String. Method name and argument list: to String, left parentheses, right parentheses, returns the name of the enum constant. Row 5. Return type: enum. Method name and argument list: value Of, left parentheses, String enum Name, right parentheses, static method that returns the enum object whose name is the same as the String argument enum Name.

Line 13, indented once: Auto sports Car, equals, new Auto, left parentheses, double quotes, Ferrari, double quotes, comma, 100, comma, 15.0, right parentheses, semicolon. Line 14, indented once: cars, left square bracket, 0, right square bracket, equals, sports Car, semicolon. 2 forward slashes, assign sports Car to element 0. Line 15, indented once: cars, left square bracket, 1, right square bracket, equals, new Auto, left parentheses, right parentheses, semicolon. 2 forward slashes, default Auto object. Line 16, indented once: 2 forward slashes, cars, left square bracket, 2, right square bracket, has not been instantiated and is null. Line 17: blank. Line 18, indented once: 2 forward slashes, call

Auto methods. Line 19, indented once: System dot out dot print l n, left parentheses, double quotes, cars, left square bracket, 0, right square bracket, is a, blank space, double quotes, plus, cars, left square bracket, 0, right square bracket, dot, get Model, left parentheses, right parentheses, right parentheses, semicolon. Line 20: blank. Line 21, indented once: Auto my Car, equals, cars, left square bracket, 1, right square bracket, semicolon. Line 22, indented once: System dot out dot print l n, left parentheses, double quotes, my Car has used, blank space, double quotes, plus, my Car dot get Gallons Of Gas, left parentheses, right parentheses. Line 23, indented multiple times: plus, double quotes, blank space, gallons of gas, double quotes, right parentheses, semicolon. Line 24: blank. Line 25, indented once: 2 forward slashes. attempt to call method when Auto object is not instantiated. Line 26, indented once: System dot out dot print l n, left parentheses, double quotes, cars, left square bracket, 2, right square bracket, is a, blank space, double quotes, plus, cars, left square bracket, 2, right square bracket, dot, get Model, left parentheses, right parentheses, right parentheses, semicolon. Line 27, indented once: right brace. Line 28: right brace.

Back to Example

The Auto class constructor summary is as follows. Auto, left parentheses, right parentheses, creates an Auto object with initial default values of double quotes, unknown, double quotes, 0, and 0.0. Auto, left parentheses, String model, comma, int miles Driven, comma, double gallons Of Gas, right parentheses, creates an Auto object with the initial values of model, miles Driven, and gallons Of Gas. The table summarizing the methods of the Auto Class has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: String. Method name and argument list: get Model, left parentheses, right parentheses, returns the value of model. Row 2. Return value: int. Method name and argument list: get Miles Driven, left parentheses, right parentheses, returns the value of miles Driven. Row 3. Return value: double. Method name and argument list: get Gallons Of Gas, left parentheses, right parentheses, returns the value of gallons Of Gas. Row 4. Return value: Auto. Method name and argument list: set Model, left parentheses, String model, right parentheses, mutator for model. Row 5. Return value: Auto. Method name and argument list: set Miles Driven, left parentheses, int miles Driven, right parentheses, mutator for miles Driven. Row 6. Return value: Auto. Method name and argument list: set Gallons Of Gas, left parentheses, double gallons Of Gas, right parentheses, mutator for gallons Of Gas. Row 7. Return value: double. Method name and argument list: miles Per Gallon, left parentheses, right parentheses, returns the gas mileage for this Auto object. Row 8. Return value: String. Method name and argument list: to String, left parentheses, right parentheses, returns a String representation of this object. Row 9. Return value:

boolean. Method name and argument list: equals, left parentheses, Object o b j, right parentheses, compares this Auto object to another object.

Back to Table

System dot out dot print l n, left parentheses, cell Bills, right parentheses, semicolon. 2 forward slashes, incorrect attempt to print array, exclamation mark.

Back to Code

for, left parentheses, int i equals 0, semicolon, i less than array Name dot length, semicolon, i plus, plus, right parentheses.

Back to Code

int i equals 0, semicolon.

Back to Code

i, plus, plus.

Back to Code

i less than array Name dot length.

Back to Code

array Name, left square bracket, i, right square bracket.

Back to Code

i less than or equal to array Name dot length.

Back to Example

The pseudocode is as follows: To sort an array with n elements in ascending order: Step 1. Consider m elements as a subarray with m equals n elements. Step 2. Find the index of a largest value in this subarray. Step 3. Swap the values of the element with the largest value and the element in the last position in the subarray. Step 4. Consider a new subarray of m equals m minus 1 elements by eliminating the last element in the previous subarray. Step 5. Repeat steps 2 through 4 until m equals 1.

Line 7: left brace, r v 1, comma, new Auto, left parentheses, right parentheses, right brace, comma. Line 8: left brace, sedan 2, comma, sedan 3, right brace, right brace, semicolon.

Back to Code

Line 1: char, left square bracket, right square bracket, left square bracket, right square bracket, grades, semicolon. 2 forward slashes, declare the array. Line 2: grades, equals, new char, left square bracket, 4, right square bracket, left square bracket, right square bracket, semicolon. 2 forward slashes, instantiate the array. Line 3: 2 forward slashes, grades has 4 null array elements.

Back to Code

Line 4: grades, left square bracket, 0, right square bracket, equals, new char, left square bracket, 23, right square bracket, semicolon. 2 forward slashes, instantiate row 0, semicolon, 23 char elements. Line 5: grades, left square bracket, 1, right square bracket, equals, new char, left square bracket, 16, right square bracket, semicolon. 2 forward slashes, instantiate row 1, semicolon, 16 char elements. Line 6: grades, left square bracket, 2, right square bracket, equals, new char, left square bracket, 12, right square bracket, semicolon. 2 forward slashes, instantiate row 2, semicolon, 12 char elements. Line 7: grades, left square bracket, 3, right square bracket, equals, new char, left square bracket, 28, right square bracket, semicolon. 2 forward slashes, instantiate row 3, semicolon, 28 char elements.

Back to Code

grades, equals, new char, left square bracket, 4, right square bracket, left square bracket, right square bracket, semicolon.

Back to Code

The syntax is as follows: array Name, left square bracket, e x p 1, right square bracket, left square bracket, e x p 2, right square bracket. The caption below the syntax is as follows: where e x p 1 and e x p 2 are expressions that evaluate to integers.

Back to Code

The syntax is as follows: array Name dot length.

Back to Code

The syntax is as follows: array Name, left square bracket, i, right square bracket, dot, length.

Back to Code

The table has 2 columns labeled Array Element and Syntax. The row entries are as follows. Row 1. Array Element: Row 0, column j. Syntax: array Name, left square bracket, 0, right square bracket, left square bracket, j, right square bracket. Row 2. Array Element: Row i, column j. Syntax: array Name, left square bracket, i, right square bracket, left square bracket, j, right square bracket. Row 3. Array Element: Last row, column j. Syntax: array Name, left square bracket, array Name, dot, length, minus 1, right square bracket, left square bracket, j, right square bracket. Row 4. Array Element: Last row, last column. Syntax: array Name, left square bracket, array Name dot length minus 1, right square bracket, left square bracket, array Name, left square bracket, array Name dot length minus 1, right square bracket, dot, length minus 1, right square bracket. Row 5. Array Element: Number of rows in the array. Syntax: array Name dot length. Row 6. Array Element: Number of columns in row i. Syntax: array Name, left square bracket, i, right square bracket, dot, length.

Back to Table

The table has 3 rows and 4 columns. The rows are labeled July, August, and September from top to bottom. The columns are labeled Joe, Jane, Mike, and Sarah from left to right. The row entries are as follows. Row 1. July. Joe: 45.24. Jane: 54.67. Mike: 32.55. Sarah: 25.61. Row 2. August. Joe: 65.29. Jane: 49.75. Mike: 32.08. Sarah: 26.11. Row 3. September. Joe: 75.24. Jane: 54.53. Mike: 34.55. Sarah: 28.16.

Back to Table

Program code. The code contains the following keywords: public, class, static, void, String, final, int, double, new, for. Line 1: Forward slash. Asterisk. Two hyphen Dimensional array of Cell Phone Bills. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk.

Forward slash. Line 4: blank. Line 5: public class Family Cell Bills. Line 6: left brace. Line 7, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 8, indented once: left brace. Line 9, indented twice: 2 forward slashes, declare constants for the number of rows and columns. Line 10, indented once: final int NUMBER underscore OF underscore MONTHS, equals, 3, semicolon. Line 11, indented once: final int NUMBER underscore OF underscore PERSONS, equals, 4, semicolon. Line 12: blank. Line 13, indented once: 2 forward slashes, declare and instantiate the array. Line 14, indented once: double, left square bracket, right square bracket, left square bracket, right square bracket, family Cell Bills, equals. Line 15, indented twice: new double, left square bracket, NUMBER underscore OF underscore MONTHS, right square bracket, left square bracket, NUMBER underscore OF underscore PERSONS, right square bracket, semicolon. Line 16: blank. Line 17, indented once: 2 forward slashes. assign values to array elements. Line 18, indented once: family Cell Bills, left square bracket, 0, right square bracket, left square bracket, 0, right square bracket, equals, 45.24, semicolon. 2 forward slashes, row 0. Line 19, indented once: family Cell Bills, left square bracket, 0, right square bracket, left square bracket, 1, right square bracket, equals, 54.67, semicolon. Line 20, indented once: family Cell Bills, left square bracket, 0, right square bracket, left square bracket, 2, right square bracket, equals, 32.55, semicolon.Line 21, indented once: family Cell Bills, left square bracket, 0, right square bracket, left square bracket, 3, right square bracket, equals, 25.61, semicolon. Line 22: blank. Line 23, indented once: family Cell Bills, left square bracket, 1, right square bracket, left square bracket, 0, right square bracket, equals, 65.29, semicolon. 2 forward slashes, row 1. Line 24, indented once: family Cell Bills, left square bracket, 1, right square bracket, left square bracket, 1, right square bracket, equals, 49.75, semicolon. Line 25, indented once: family Cell Bills, left square bracket, 1, right square bracket, left square bracket, 2, right square bracket, equals, 32.08, semicolon. Line 26, indented once: family Cell Bills, left square bracket, 1, right square bracket, left square bracket, 3, right square bracket, equals, 26.11, semicolon. Line 27: blank. Line 28, indented once: family Cell Bills, left square bracket, 2, right square bracket, left square bracket, 0, right square bracket, equals, 75.24, semicolon. 2 forward slashes, row 2. Line 29, indented once: family Cell Bills, left square bracket, 2, right square bracket, left square bracket, 1, right square bracket, equals, 54.53, semicolon. Line 30, indented once: family Cell Bills, left square bracket, 2, right square bracket, left square bracket, 2, right square bracket, equals, 34.55, semicolon. Line 31, indented once: family Cell Bills, left square bracket, 2, right square bracket, left square bracket, 3, right square bracket, equals, 28.16, semicolon. Line 32: blank. Line 33, indented once: System dot out dot print l n, left parentheses, double quotes, The first monthly cell bill for the first, double quotes. Line 34, indented twice: plus, double quotes, family member is, backslash, n, double quotes. Line 35, indented twice: plus, family Cell Bills, left square bracket, 0, right square bracket, left square bracket, 0, right square bracket, right parentheses, semicolon. Line 36, indented once: System dot out dot print l n, left parentheses, double quotes, The last monthly cell bill for the last, blank space, double quotes. Line 37, indented twice: plus, double quotes, family member is, backslash, n, double quotes. Line 38, indented twice: plus, family Cell Bills, left square bracket, NUMBER underscore OF underscore MONTHS minus 1, right square bracket, left square bracket, NUMBER underscore OF underscore PERSONS minus 1, right square bracket, right parentheses, semicolon. Line 39: blank. Line 40, indented once: int num Rows, equals, family Cell Bills dot length, semicolon. Line 41, indented once: System dot out dot print l n, left parentheses, double quotes, backslash n, The number of rows is, double quotes, plus, num Rows, right parentheses, semicolon. Line 42: blank. Line 43, indented once: for, left parentheses, int i equals 0, semicolon, i less than num Rows, semicolon, i plus, plus, right parentheses. Line 44, indented once: left brace. Line 45, indented twice: System dot out dot print, left parentheses, double quotes, The number of columns in row, double quotes, plus, i, plus, double quotes, blank space, is, double quotes, right parentheses, semicolon. Line 46, indented twice: System dot out dot print l n, left parentheses, family Cell Bills, left square bracket, i, right square bracket, dot, length, right parentheses, semicolon. Line 47, indented twice: right brace. Line 48, indented once: right brace. Line 49: right brace.

Back to Example

a r r, left square bracket, a r r dot length, minus, 1, right square bracket, left square bracket, a r r, left square bracket, a r r dot length minus 1, right square bracket, dot length minus 1, right square bracket.

Back to Code

Line 1: 2 forward slashes. invalid row indexes for the family cell Bills array, 2 exclamation marks. Write your code here, colon. Line 64: return 0, comma, semicolon. 2 Forward slashes. replace this line with your return statement. Line 65: Right brace. 2 Forward slashes. end of find Minimum n method. Line 66: 2 Forward slashes. 5 asterisks, 5. Student writes this method. Line 67: Forward slash, comma, 2 asterisks. Finds the number of times value is found in the array. Line 68: Asterisk. The instance variable named int Array is the integer array. Line 69: Asterisk. at symbol param value the value to count. Line 70: Asterisk. at symbol return the number of times value was found. Line 71: Asterisk, comma, Forward slash. Line 72: public int count Found, left parentheses, int value , right parentheses. Line 73: Left brace. Line 74: 2 Forward slashes. Note: To animate the algorithm, comma, put this method call as the. Line 75: 2 Forward slashes. last statement in your inner for loop. Line 76: 2 Forward slashes. animate, left parentheses, row, comma, column, comma, num, right parentheses, comma, semicolon. Line 77: 2 Forward slashes. where row is the index of the array's current row. Line 78: 2 Forward slashes. column is the index of the array's current column. Line 79: 2 Forward slashes. num is the local variable storing the current frequency. Line 80: 2 Forward slashes. count. Line 81: 2 Forward slashes. Write your code here, colon. Line 82: return 0, comma, semicolon. 2 Forward slashes. replace this line with your return statement. Line 83: Right brace. Line 84: 2 Forward slashes. end of count Found method.

Back to Example

animate, left parentheses, row, comma, column, right parentheses, semicolon.

Back to Code

The table has 2 columns labeled Dimension and Array Element. The row entries are as follows. Row 1. Dimension: first. Array Element: array Name, left square bracket, i subscript 1, right square bracket, is an, left parentheses, n minus 1, right parentheses, hyphen, dimensional array. Row 2. Dimension: second. Array Element: array Name, left square bracket, i subscript 1, right square bracket, left square bracket, i subscript 2, right square bracket, is an, left parentheses, n minus 2, right parentheses, hyphen, dimensional array. Row 3. Dimension: k superscirpt t h. Array Element: array Name, left square bracket, i subscript 1, right square bracket, left square bracket, i subscript 2, right square bracket, left square bracket, i subscript 3, right square bracket, left square bracket, dot, dot, dot, right square bracket, left square bracket, i subscript k, right square bracket, is an, left parentheses, n minus k, right parentheses, multi, hyphen, dimensional array. Row 4. Dimension: left square bracket, n minus 2, right square bracket, superscript t h. Array Element: array Name, left square bracket, i subscript 1, right square bracket, left square bracket, i subscript 2, right square bracket, left square bracket, i subscript 3, right square bracket, left square bracket, dot, dot, dot, right square bracket, left square bracket, i subscript n minus 2, right square bracket, is a two, hyphen, dimensional array. Row 5. Dimension: left square bracket, n minus 1, right square bracket, superscript t h. Array Element: array Name, left square bracket, i subscript 1, right square bracket, left square bracket, i subscript 2, right square bracket, left square bracket, i subscirpt 3, right square bracket, left square bracket, dot, dot, dot, right square bracket, left square bracket, i subscript n minus 1, right square bracket, is a single hyphen dimensional array. Row 6. Dimension: n superscript t h. Array Element: array Name, left square bracket, i subscript 1, right square bracket, left square bracket, i subscript 2, right square bracket, left square bracket, i subscript 3, right square bracket, left square bracket, dot, dot, dot, right square bracket, left square bracket, i subscript n minus 1, right square bracket, left square bracket, i subscript n, right square bracket, is an array element.

Back to Table

Line 1: double, left square bracket, right square bracket, left square bracket, right square bracket, left square bracket, right square bracket, sales, semicolon. 2 forward slashes, declare a four hyphen dimensional array. Line 2: Sales equals new double, left square bracket, 10, right square bracket, left square bracket, 52, right square bracket, left square bracket, 7, right square bracket, semicolon. 2 forward slashes, instantiate the array. Line 3: Sales, left square bracket, 0, right square bracket, left square bracket, 0, right square bracket, left square bracket, 0, right square bracket, equals, 638.50, semicolon, 2 forward slashes, access the first element. Line 4: sales, left square bracket, 4, right square bracket, left square bracket, 22, right square bracket, left square bracket, 3, right square bracket, equals, 928.30, semicolon. 2 forward slashes, access another element. Line 5: sales, left square bracket, 9, right square bracket, left square bracket, 51, right square bracket, left square bracket, 6, right square bracket, equals, 1234.90, semicolon. 2 forward slashes, access the last element.

Back to Code

Program code. The code contains the following keywords: for, int. Line 1: for, left parentheses, int i equals 0, semicolon, i less than array Name dot length, semicolon, i plus, plus, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int j equals 0, semicolon, j less than array Name, left square bracket, i, right square bracket, dot, length, semicolon, j plus, plus, right parentheses. Line 4, indented once: left brace. Line

5, indented twice: for, left parentheses, int k equals 0, semicolon, k less than array Name, left square bracket, i, right square bracket, left square bracket, j, right square bracket, dot, length, semicolon, k plus, plus, right parentheses. Line 6, indented twice: left brace. Line 7, indented thrice: 2 forward slashes, access and process the element array Name, left square bracket, i, right square bracket, left square bracket, j, right square bracket, left square bracket, k, right square bracket. Line 8, indented twice: right brace. Line 9, indented once: right brace. Line 10: right brace.

Back to Code

Program code. The code contains the following keywords: for, int. Line 1: for, left parentheses, int i equals 0, semicolon, i less than sales dot length, semicolon, i plus, plus, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int j equals 0, semicolon, j less than array Name, left square bracket, i, right square bracket, dot, length, semicolon, j plus, plus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: for, left parentheses, int k equals 0, semicolon, k less than array Name, left square bracket, i, right square bracket, left square bracket, j, right square bracket, dot, length, semicolon, k plus, plus, right parentheses. Line 6, indented twice: left brace. Line 7, indented thrice: for, left parentheses, int l equals 0, semicolon, l less than array Name, left square bracket, i, right square bracket, left square bracket, j, right square bracket, left square bracket, k, right square bracket, dot, length, semicolon, l plus, plus, right parentheses. Line 8, indented thrice: left brace. Line 9, indented four times: 2 forward slashes, process element array Name, left square bracket, i, right square bracket, left square bracket, j, right square bracket, left square bracket, k, right square bracket, left square bracket, l, right square bracket. Line 10, indented thrice: right brace. Line 11, indented twice: right brace. Line 12, indented once: right brace. Line 13: right brace.

Back to Code

import java dot util dot Array List, semicolon.

Back to Code

The syntax is as follows: Array List, left angled bracket, Class Name, right angled bracket, array List Name, semicolon.

Back to Code

Line 1: Array List, left angled bracket, String, right angled bracket, list Of Strings, semicolon. Line 2: Array List, left angled bracket, Auto, right angled bracket, list Of Cars, semicolon.

Back to Code

Array List, left angled bracket, int, right angled bracket, list

Of Ints, semicolon.

Back to Code

Line 1: Test dot java, colon, 7, colon, error, colon, unexpected type. Line 2, indented once: Array List, left angled bracket, int, right angled bracket, list Of Ints, semicolon. Line 3: a caret sign under lowercase i following the left angled bracket in Line 2. Line 4: required, colon, reference. Line 5: found, colon, int. Line 6: 1 error.

Back to Code

The title of the table reads: Array List Constructors Summary. The constructor name and argument list are as follows. Row 1. Array List, left angled bracket, Class Name, right angled bracket, left parentheses, right parentheses, constructs an Array List object of Class Name type with an initial capacity of 10. Row 2. Array List, left angled bracket, Class Name, right angled bracket, left parentheses, int initial Capacity, right parentheses, constructs an Array List object of Class Name type with the specified initial capacity.

Back to Table

The syntax is as follows. array List Name, equals, new, Array List, left angled bracket, Class Name, right angled bracket, left parentheses, right parentheses, semicolon. The caption below the syntax is as follows: where Class

Name is the class type of the objects that will be stored in the Array List and array List Name has been declared previously as an Array List reference for that class.

Back to Code

Line 1: list Of Strings, equals, new Array List, left angled bracket, String, right angled bracket, left parentheses, right parentheses, semicolon. Line 2: list Of Cars, equals, new Array List, left angled bracket, Auto, right angled bracket, left parentheses, right parentheses, semicolon.

Back to Code

list Of Cars, equals, new, Array List, left parentheses, right parentheses, semicolon.

Back to Code

Line 1: Test dot java, colon, 11, colon, warning, colon, left square bracket, raw types, right square bracket, found raw type, colon, Array List. Line 2, indented once: list Of Cars, equals, new Array List, left parentheses, right parentheses, semicolon. Line 3: a caret sign under uppercase A in Line 2. Line 4, indented once: missing type arguments for generic class Array List, left angled bracket, uppercase e, right angled bracket. Line 5, indented once: where uppercase e is a type hyphen variable, colon. Line 6, indented twice: uppercase e extends object declared in class Array List. Line 7: blank. Line 8: Test dot java, colon, 11, colon, warning, colon, left square bracket, unchecked, right square bracket, unchecked conversion. Line 12, indented once: list Of Cars, equals, new Array List, left parentheses, right parentheses, semicolon. Line 13: a caret sign under lowercase n of new in Line 12. Line 14, indented once: required, colon, Array List, left angled bracket, Auto, right angled bracket. Line 15, indented once: found, colon, Array List. Line 16: 2 warnings.

Back to Code

Line 1: Array List, left angled bracket, String, right angled bracket, list Of Strings, 1, semicolon. Line 2: list Of Strings 1, equals, new, Array List, left angled bracket, String, right angled bracket, left parentheses, 5, right parentheses, semicolon.

Back to Code

The syntax is as follows: Array List, left angled bracket, Class Name, right angled bracket, array List Name, equals, new, Array List, left angled bracket, Class Name, right angled bracket, left parentheses, right parentheses, semicolon.

Back to Code

Line 1: Array List, left angled bracket, Integer, right angled bracket, list Of Ints, equals, new, Array List, left angled bracket, Integer, right angled bracket, left parentheses, right parentheses, semicolon. Line 2: Array List, left angled bracket, String, right angled bracket, list Of Strings 2, equals, new Array List, left angled bracket, String, right angled bracket, left parentheses, right parentheses, semicolon.

Back to Code

The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: boolean. Method name and argument list: add, left parentheses, uppercase e, underlined, element, right parentheses, appends the specified element to the end of the list. Row 2. Return value: uppercase e, underlined. Method name and argument list: remove, left parentheses, int index, right parentheses, removes and returns the element at the specified index position in the list. Row 3. Return value: void. Method name and argument list: clear, left parentheses, right parentheses, removes all the elements from this list. Row 4. Return value: uppercase e underlined. Method name and argument list: get, left parentheses, int index, right parentheses, returns the element at the specified index position in the list; the element is not removed from the list. Row 5. Return value: uppercase e underlined. Method name and argument list: set, left parentheses, int index, comma, uppercase e underlined element, right parentheses, replaces the element at the specified index position in this list with the specified element. Row 6. Return value: int. Method name and argument list: size, left parentheses, right parentheses, returns the number of elements in this list. Row 7. Return value: void. Method name and argument list: trim To Size, left parentheses, right parentheses, sets the capacity to the list's current size.

Back to Table

Program code. The code contains the following keywords: for, int. Line 1: Class Name current Object, semicolon. Line 2: for, left parentheses, int i equals 0, semicolon, i less than array List Name dot size, left parentheses, right parentheses, semicolon, i plus, plus, right parentheses. Line 3: left brace. Line 4, indented once: current Object equals array List Name dot get, left parentheses, i, right parentheses, semicolon. Line 5, indented once: 2 forward slashes, process current Object. Line 6: right brace.

Back to Code

Program code. The code contains the following keywords: String, for, int. Line 1: String current String, semicolon. Line 2: for, left parentheses, int i equals 0, semicolon, i less than list Of Strings dot size, left parentheses, right parentheses, semicolon, i plus, plus, right parentheses. Line 3: left brace. Line 4, indented once: current String, equals, list Of Strings dot get, left parentheses, i, right parentheses, semicolon. Line 5, indented once: 2 forward slashes, process current String. Line 6: right brace.

Back to Code

Program code. The code contains the keyword for. Line 1: for, left parentheses, Class Name current Object, colon, array List Name, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes. process current Object. Line 4: right brace.

Back to Code

Program code. The code contains the keyword for, String. Line 1: for, left parentheses, String current String, colon, names, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes. process current String. Line 4: right brace.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, for, int. Line 1: Forward slash. Asterisk. A Simple Array List of Integers. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk. Forward slash. Line 4: blank. Line 5: import java dot util dot Array List, semicolon. Line 6: blank. Line 7: public class Array List Of Integers. Line 8: left brace. Line 9, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 10, indented once: left brace. Line 11, indented twice: Array List, left angled bracket, Integer, right angled bracket, list, equals, new Array List, left angled bracket, Integer, right angled bracket, left parentheses, right parentheses, semicolon.

The first table is titled, Auto Class Constructor Summary. The row entries are as follows. Row 1. Auto, left parentheses, right parentheses, creates an Auto object with initial default values of, double quotes, unknown, double quotes, 0, and 0.0. Row 2. Auto, left parentheses, String model, comma, int miles Driven, comma, double gallons Of Gas, right parentheses, creates an Auto object with the initial values of model, miles Driven, and gallons Of Gas. The second table is titled, Auto Class Method Summary. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: String. Method name and argument list: get Model, left parentheses, right parentheses, returns the value of model. Row 2. Return value: int. Method name and argument list: get Miles Driven, left parentheses, right parentheses, returns the value of miles Driven. Row 3. Return value: double. Method name and argument list: get Gallons Of Gas, left parentheses, right parentheses, returns the value of gallons Of Gas. Row 4. Return value: Auto. Method name and argument list: set Model, left parentheses, String model, right parentheses, mutator for model. Row 5. Return value: Auto. Method name and argument list: set Miles Driven, left parentheses, int miles Driven, right parentheses, mutator for miles Driven. Row 6. Return value: Auto. Method name and argument list: set Gallons Of Gas, left parentheses, double gallons Of Gas, right parentheses, mutator for gallons Of Gas. Row 7. Return value: double. Method name and argument list: miles Per Gallon, left parentheses, right parentheses, returns the gas mileage for this Auto object. Row 8. Return value: String. Method name and argument list: to String, left parentheses, right parentheses, returns a String representation of this object. Row 9. Return value: boolean. Method name and argument list: equals, left parentheses, Object o b j, right parentheses, compares this Auto object to another object.

Back to Table

Line 1: 2 Forward slashes. 5 asterisks, 1. This method has been coded as an example. Line 2: Forward slash, comma, 2 asterisks. Fills the car List with hard hyphen coded Auto objects. Line 3: Asterisk. The instance variable car List is the Array List. Line 4: Asterisk. to be filled with Auto objects. Line 5: Asterisk, comma, Forward slash. Line 6: public void fill With Cars, Left parentheses, comma, right parentheses. Line 7: Left brace. Line 8: 2 Forward slashes. clear car List before adding cars. Line 9: car List dot clear, Left parentheses, comma, right parentheses, comma, semicolon. Line 10: 2 Forward slashes. Reset the number of Autos to 0. Line 11: 2 Forward slashes. This is needed so that the animation feedback works correctly. Line 12: Auto dot clear Number Autos, Left parentheses, comma, right parentheses, comma, semicolon. Line 13: Auto car 1 equals new Auto, left parentheses, double quotes, B M W double quotes, comma, 0, comma, 0.0, right parentheses, comma, semicolon. Line 14: Auto car 2 equals new Auto, left parentheses, double quotes, Ferrari double quotes, comma, 100, comma, 500.0, right parentheses, , comma, semicolon. Line 15: Auto car 3 equals new Auto, left parentheses, double quotes, Jeep double quotes, , comma, 1000, comma, 90.0, right parentheses, comma, semicolon. Line 16: Auto car 4 equals new Auto, left parentheses, double quotes, Ferrari double quotes, comma, 10, comma, 3.0 , right parentheses, comma, semicolon. Line 17: Auto car 5 equals new Auto, left parentheses, double quotes, BMW double quotes, comma, 4000, comma, 200.0, right parentheses, comma, semicolon. Line 18: Auto car 6 equals new Auto, left parentheses, double quotes, Ferrari double quotes, comma, 1000, comma, 50.0, right parentheses, comma, semicolon. Line 19: car List dot add, left parentheses, car 1, right parentheses, comma, semicolon. Line 20: animate, left parentheses, car 1, right parentheses, comma, semicolon. Line 21: car List dot add, left parentheses, car 2, right parentheses, comma, semicolon. Line 22: animate, left parentheses, car 2, right parentheses, comma, semicolon. Line 23: car List dot add, left parentheses, car 3, right parentheses, comma, semicolon. Line 24: animate, left parentheses, car 3, right parentheses, comma, semicolon. Line 25: car List dot add, left parentheses, car 4, right parentheses, comma, semicolon. Line 26: animate, left parentheses, car 4, right parentheses, comma, semicolon. Line 27: car List dot add, left parentheses, car 5, right parentheses, comma, semicolon. Line 28: animate, left parentheses, car 5, right parentheses, comma, semicolon. Line 29: car List dot add, left parentheses, car 6, right parentheses, comma, semicolon. Line 30: animate, left parentheses, car 6, right parentheses, comma, semicolon. Line 31: Right brace. Line 32: 2 Forward slashes. end of fill With Cars method. Line 33: 2 Forward slashes. 5 asterisks, 2. Student writes this method. Line 34: Forward slash, comma, 2 asterisks. Prints car List to console, comma, elements are separated by a space. Line 35: Asterisk. The instance variable car List is the Array List to be printed. Line 36: Asterisk, comma, Forward slash. Line 37: public void print

Auto List, Left parentheses, comma, right parentheses. Line 38: Left brace. Line 39: 2 Forward slashes. Note: To animate the algorithm, comma, put this method call as the. Line 40: 2 Forward slashes. last statement in your for loop. Line 41: 2 Forward slashes. animate, left parentheses, car, right parentheses, comma, semicolon. Line 42: 2 Forward slashes. where car is the variable name for the current Auto object. Line 43: 2 Forward slashes. as you loop through the Array List object. Line 44: 2 Forward slashes. Write your code here, colon. Line 45: Right brace. Line 46: 2 Forward slashes. end of print Auto List method. Line 47: 2 Forward slashes. 5 asterisks, 3. Student writes this method. Line 48: Forward slash, comma, 2 asterisks. Sets the model of all the elements in car List to parameter. Line 49: value. Line 50: Asterisk. The instance variable car List is the Array List to be modified. Line 51: Asterisk. at symbol param model the model to assign to all Auto objects in car List. Line 52: Asterisk, comma, Forward slash. Line 53: public void set Model Values, left parentheses, String model, right parentheses. Line 54: Left brace. Line 55: 2 Forward slashes. Note: To animate the algorithm, comma, put this method call as the. Line 56: 2 Forward slashes. last statement in your for loop. Line 57: 2 Forward slashes. animate, left parentheses, car, right parentheses, comma, semicolon. Line 58: 2 Forward slashes. where car is the variable name for the current Auto object. Line 59: 2 Forward slashes. as you loop through the Array List object. Line 60: 2 Forward slashes. Write your code here, colon. Line 61: Right brace. Line 62: 2 Forward slashes. end of set Model Values method. Line 63: 2 Forward slashes. 5 asterisks, 4. Student writes this method. Line 64: Forward slash, comma, 2 asterisks. Finds maximum number of miles driven. Line 65: Asterisk. Instance variable car List is the Array List to search. Line 66: Asterisk. at symbol return the maximum miles driven by all the Auto objects. Line 67: Asterisk, comma, Forward slash. Line 68: public int find Maximum Miles Driven, Left parentheses, comma, right parentheses. Line 69: Left brace. Line 70: 2 Forward slashes. Note: To animate the algorithm, comma, put this method call as the. Line 71: 2 Forward slashes. last statement in your for loop. Line 72: 2 Forward slashes. animate, left parentheses, car, comma, maximum, right parentheses, comma, semicolon. Line 73: 2 Forward slashes. where car is the variable name for the current Auto object. Line 74: 2 Forward slashes. and maximum is the int variable storing the current maximum. Line 75: 2 Forward slashes. number of miles for all Auto elements you have already tested. Line 76: 2 Forward slashes. as you loop through the Array List object. Line 77: 2 Forward slashes. Write your code here, colon. Line 78: return 0, comma, semicolon. 2 Forward slashes. replace this statement with your return statement. Line 79: Right brace. Line 80: 2 Forward slashes. end of find Maximum Miles Driven method. Line 81: 2 Forward slashes. 5 asterisks, 5. Student writes this method. Line 82: Forward slash, comma, 2 asterisks. Finds number of times parameter model is found in the car List. Line 83: Asterisk. Instance variable car List is the Array List in which we search. Line 84: Asterisk. at symbol param model the model to count. Line 85: Asterisk. at symbol return the number of times model was found. Line 86: Asterisk, comma, Forward slash. Line 87: public int count Found, left parentheses, String model, right parentheses. Line 88: Left brace. Line 89: 2 Forward slashes. Note, colon, To animate the algorithm, comma, put this method call as the. Line 90: 2 Forward slashes. last statement in your for loop. Line 91: 2 Forward slashes. animate, left parentheses, car, comma, num , right parentheses, comma, semicolon. Line 92: 2 Forward slashes. where car is the variable name for the current Auto object. Line 93: 2 Forward slashes. and num is the int variable storing the current number of. Line 94: 2 Forward slashes. Auto elements whose model is equal to the method's. Line 95: parameter. Line 96: 2 Forward slashes. as you loop through the Array List object. Line 97: 2 Forward slashes. Write your code here, colon. Line 98: return 0, comma, semicolon. 2 Forward slashes. replace this statement with your return statement. Line 99: Right brace. Line 100: 2 Forward slashes. end of count Found method.

Back to Example

Line 1: animate, left parentheses, car, right parentheses, semicolon. 2 forward slashes, or. Line 2: animate, left parentheses, car, comma, maximum, right parentheses, semicolon. 2 forward slashes, or. Line 3: animate, left parentheses, car, comma, num, right parentheses, semicolon.

Back to Code

The syntax is as follows: Hash Map, left angled bracket, Class Name 1, comma, Class Name 2, right angled bracket, hash Map Name, semicolon.

Back to Code

Line 1: Hash Map, left angled bracket, String, comma, String, right angled bracket, countries, semicolon. Line 2: Hash Map, left angled bracket, Integer, comma, Auto, right angled bracket, cars, semicolon.

Back to Code

The table lists the constructor name and argument list. The row entries are as follows. Row 1. Hash Map, left angled bracket, Class Name 1, comma, Class Name 2, right angled bracket, left parentheses, right parentheses. Constructs a Hash Map object whose keys are Class Name 1 objects and values are Class Name 2 objects. Row 2. Hash Map, left angled bracket, Class Name 1, comma, Class Name 2, right angled bracket, left parentheses, int initial Capacity, right parentheses. Constructs a Hash Map object whose keys are Class Name 1 objects and values are Class Name 2 objects. The resulting Hash Map object has teh specified initial capacity and a default load factor of 0.75. A load factor of

0.75 means that if the capacity of the Hash Map is 75 percent full, the capacity will be automatically increased.

Back to Table

The syntax is as follows. hash Map Name, equals, new Hash Map, left angled bracket, Class Name 1, comma, Class Name 2, right angled bracket, left parentheses, argument list, right parentheses, semicolon.

Back to Code

Line 1. countries, equals, new Hash Map, left angled bracket, String, comma, String, right angled bracket, left parentheses, right parentheses, semicolon. Line 2. cars, equals, new Hash Map, left angled bracket, String, comma, Auto, right angled bracket, left parentheses, 10, right parentheses, semicolon.

Back to Code

The title of the table is Useful Methods of the Hash Map Class. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: uppercase v. Method name and argument list: put, left parentheses, uppercase k key, comma, uppercase v value, right parentheses, Adds the, left parentheses, key, comma, value, right parentheses, pair specified to this Hash Map. If this Hash Map previously contained key, the old value is replaced and returned. Returns null if there was no previous mapping for key. uppercase k and uppercase v are the data types for the keys and the values of this Hash Map, respectively. Row 2. Return value: uppercase v. Method name and argument list: get, left parentheses, uppercase k key, right parentheses, Returns the value mapped to key, null if there is no value mapped to key. Row 3. Return value: boolean. Method name and argument list: is Empty, left parentheses, right parentheses, Returns true if this Hash Map contains no mapping, false otherwise. Row 4. Return value: uppercase v. Method name and argument list: remove, left parentheses, uppercase k key, right parentheses, Removes the, left parentheses, key, comma, value, right parentheses, pair if key is found and returns the value mapped to key. Returns null if no mapping exists for key. Row 5. Return value: boolean. Method name and argument list: replace, left parentheses, uppercase k key, comma, uppercase v old Value, comma, uppercase v new Value, right parentheses, changes old Value to new Value if old Value is mapped to key in this Hash Map; if it is, it returns true, false otherwise. Row 6. Return value: int. Method name and argument list: size, left parentheses, right parentheses, Returns the number of, left parentheses, key, comma, value, right parentheses, pairs in this Hash Map. Row 7. Return value: boolean. Method name and argument list: contains, left parentheses, uppercase k key, right parentheses, Returns true if key is a key in this Hash Map, false otherwise. Row 8. Return value: boolean. Method name and argument list: contains, left parentheses, uppercase v value, right parentheses, Returns true if value is mapped to one or more keys in this Hash Map, false otherwise. Row 9. Return value: Set, left angled bracket, uppercase k, right angled bracket. Method name and argument list: key Set, left parentheses, right parentheses, Returns a Set of keys contained in this Hash Map. Row 10. Return value: Collection, left angled bracket, uppercase v, right angled bracket. Method name and argument list: values, left parentheses, right parentheses, Returns a collection of values contained in this Hash Map.

Back to Table

Program code. The code contains the following keywords: import, public, class, static, void, String, for. Line 1: Forward slash. Asterisk. A simple Hash Map of, left parentheses, String, comma, String, right parentheses, pairs. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk. Forward slash. Line 4: blank. Line 3: a dot add, left parentheses, single quote, uppercase a, single quote, right parentheses, semicolon. Line 4: a dot add, left parentheses, single quote, uppercase v, single quote, right parentheses, semicolon. Line 5: a dot add, left parentheses, single quote, uppercase a, single quote, right parentheses, semicolon. Line 6: a dot set, left parentheses, 1, comma, single quote, uppercase j, single quote, right parentheses, semicolon. Line 7: for, left parentheses, Character, c, colon, a, right parentheses. Line 8, indented once: System dot out dot print, left parentheses, c plus, double quotes, blank space, double quotes, right parentheses, semicolon.

Back to Code

The text magnified by the lens reads: Look It Up.

Back to Figure

Program code. The code contains the following keywords: import, public, class, final, new, private, double, return, if, this, String. Line 1: Forward slash, 2 asterisks. Bank Account class, comma, version 1. Line 2: Asterisk. Tab space. Anderson, comma, Franceschi. Line 3: Asterisk. Tab space. Represents a generic bank account. Line 4: Asterisk, forward slash. Line 5: import java dot text dot Decimal Format, semicolon. Line 6: blank. Line 7: public class Bank Account. Line 8: left brace. Line 9, indented once: public final Decimal Format MONEY. Line 10, indented multiple times: equals, new, Decimal Format, left parentheses, double quotes, dollar sign, hash, comma, 2 hashes, 0, decimal point, 0 0, double quotes, right parentheses, semicolon. Line 11, indented once: private double balance, semicolon. Line 12: blank. Line 13, indented once: Forward slash, 2 asterisks, default constructor. Line 14, indented once: asterisk, blank space, sets balance to 0, decimal point, 0. Line 15, indented once: Asterisk, forward slash. Line 16, indented once: public Bank Account, left parentheses, right parentheses. Line 17, indented once: left brace. Line 18, indented twice: balance, equals, 0.0, semicolon. Line 19, indented once: right brace. Line 20: blank. Line 21, indented once: Forward slash, 2 asterisks, overloaded constructor. Line 22, indented once: asterisk, blank spaces, at symbol, param balance begining balance. Line 23, indented once: asterisk, forward slash. Line 24, indented once: public Bank Account, left parentheses, double balance, right parentheses. Line 25, indented once: left brace. Line 26, indented twice: deposit, left parentheses, balance, right parentheses, semicolon. Line 27, indented once: right brace. Line 28: blank. Line 29, indented once: Forward slash, 2 asterisks, accessor for balance. Line 30, indented once: asterisk, blank spaces, at symbol, return current account balance. Line 31, indented once: Asterisk, forward slash. Line 32, indented once: public double get Balance, left parentheses, right parentheses. Line 33, indented once: left brace. Line 34, indented twice: return balance, semicolon. Line 35, indented once: right brace. Line 36: blank. Line 37, indented once: Forward slash, 2 asterisks, deposit amount to account. Line 38, indented once: Asterisk, blank spaces, at symbol, param amount amount to deposit, semicolon. Line 39, indented once: Asterisk, blank spaces, amount must be, greater than or equal to 0.0. Line 40, indented once: Asterisk, blank spaces, at symbol, return a reference to this object. Line 41, indented once: Asterisk, forward slash. Line 42, indented once: public Bank Account deposit, left parentheses, double amount, right parentheses. Line 43, indented once: left brace. Line 44, indented twice: if, left parentheses, amount greater than or equal to 0.0, right parentheses. Line 45, indented thrice: balance, plus, equals, amount, semicolon. Line 46: blank. Line 47, indented twice: return this, semicolon. Line 48, indented once: right brace. Line 49: blank. Line 50, indented once: Forward slash, 2 asterisks. withdraw amount from account. Line 51, indented once: asterisk, blank spaces, at symbol, param amount, blank spaces, amount to withdraw, semicolon. Line 52, indented once: Asterisk, blank spaces, amount must be greater than or equal to 0.0. Line 53, indented once: Asterisk, blank spaces, amount must be less than or equal to balance. Line 54, indented once: asterisk, blank spaces, at symbol, return a reference to this object. Line 55: Asterisk. Forward slash. Line 56, indented once: public Bank Account withdraw, left parentheses, double amount, right parentheses. Line 56, indented once: left brace. Line 58, indented twice: if, left parentheses, amount greater than or equal to 0.0, 2 ampersands, amount less than or equal to balance, right parentheses. Line 59, indented thrice: balance, minus, equals, amount, semicolon. Line 60: blank. Line 61, indented twice: return this, semicolon. Line 62, indented once: right brace. Line 63: blank. Line 64, indented once: Forward slash, 2 asterisks, to String. Line 65, indented once: Asterisk, blank spaces, at symbol, return the balance formatted as money. Line 66, indented once: Asterisk. Forward slash. Line 67, indented once: at symbol, Override. Line 68, indented once: public String to String, left parentheses, right parentheses. Line 69, indented once: left brace. Line 70, indented twice: return, double quotes, balance is, double quotes, plus, MONEY dot format, left parentheses, balance, right parentheses, semicolon. Line 71, indented once: right brace. Line 72: right brace.

Back to Example

Program code. The code contains the following keywords: public, class, extends. Line 1: Forward slash, asterisk. Checking Account class, comma, Version 1. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk, Forward slash. Line 4: blank. Line 5: public class Checking Account extends Bank Account. Line 6: left brace, right brace.

Back to Example

The table has 4 columns labeled Superclass Members, Inherited by Subclass, question mark, Directly Accessible by Subclass, question mark, Directly Accessible by Client of Subclass, question mark. The row entries are as follows. Row 1. Superclass Members: public fields. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by using field name. Directly Accessible by Client of Subclass, question mark: yes. Row 2. Superclass Members: public methods. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by calling method from other subclass methods. Directly Accessible by Client of Subclass, question mark: yes. Row 3. Superclass Members: protected fields. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by using field name. Directly Accessible by Client of Subclass, question mark: no, must use accessors and mutators. Row 4. Superclass Members: protected methods. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by calling method from subclass methods. Directly Accessible by Client of Subclass, question mark: no. Row 5. Superclass Members: private fields. Inherited by Subclass, question mark: no. Directly Accessible by Subclass, question mark: no, must use accessors and mutators. Directly Accessible by Client of Subclass, question mark: no, must use accessors and mutators. Row 6. Superclass Members: private methods. Inherited by Subclass, question mark: no. Directly Accessible by Subclass, question mark: no. Directly

Accessible by Client of Subclass, question mark: no.

The table has 4 columns labeled Superclass Members, Inherited by Subclass, question mark, Directly Accessible by Subclass, question mark, Directly Accessible by Client Subclass, question mark. The row entries are as follows. Row 1. Superclass Members: public fields. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by using field name. Directly Accessible by Client Subclass, question mark: yes. Row 2. Superclass Members: public methods. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by calling method from other subclass methods. Directly Accessible by Client Subclass, question mark: yes, by calling method using subclass object reference. Row 3. Superclass Members: protected fields. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by using field name. Directly Accessible by Client Subclass, question mark: no, must use accessors and mutators. Row 4. Superclass Members: protected methods. Inherited by Subclass, question mark: yes. Directly Accessible by Subclass, question mark: yes, by calling method from subclass methods. Directly Accessible by Client Subclass, question mark: no. Row 5. Superclass Members: private fields. Inherited by Subclass, question mark: no. Directly Accessible by Subclass, question mark: no, must use accessors and mutators. Directly Accessible by Client Subclass, question mark: no, must use accessors and mutators. Row 6. Superclass Members: private methods. Inherited by Subclass, question mark: no. Directly Accessible by Subclass, question mark: no. Directly Accessible by Client Subclass, question mark: no. Row 7. Superclass Members: constructors. Inherited by Subclass, question mark: no. Directly Accessible by Subclass, question mark: yes, using, super, left parentheses, a r g list, right parentheses, in a subclass constructor. Directly Accessible by Client Subclass, question mark: no. Row 8. Superclass Members: public or protected inherited methods that have been overridden in the subclass. Inherited by Subclass, question mark: no. Directly Accessible by Subclass, question mark: yes, using, super dot method Name, left parentheses, a r g list, right parentheses. Directly Accessible by Client Subclass, question mark: no.

The row entries are as follows. Row 1. abstract classes. Classes must be declared abstract if the class contains any abstract methods. Abstract classes can be extended. Abstract classes cannot be used to instantiate objects. Row 2. abstract methods within classes. abstract methods cannot be declared within a non-abstract class. An abstract method must consist of a method header followed by a semicolon. Abstract methods cannot be declared as private or static. A constructor cannot be declared abstract.

The title of the table reads: Useful Static Methods of the Character Class. The table has 2 columns labeled Return Value and Method name and argument list. The row entries are as follows. Row 1. Return value: boolean. Method name and argument list: is Digit, left parentheses, char c h, right parentheses, returns true if c h represents a digit from 0 to 9; false otherwise. Row 2. Return value: boolean. Method name and argument list: is Letter, char c h, right parentheses, returns true if c h represents a letter from lowercase a to lowercase z or uppercase a to uppercase z; false otherwise. Row 3. Return value: int. Method name and argument list: get Numeric Value, left parentheses, char c h, right parentheses, returns the integer value of the specified Unicode character c h.

The table is titled, Methods of Exception Classes. The table has 2 columns labeled Return Value and Method Name and Argument List. The row entries are as follows.

Row 1. Return Value: String. Method Name And Exception List: get Message, left parentheses, right parentheses, returns a message indicating the cause of the exception. Row 2. Return Value: String. Method Name And Exception List: to String, left parentheses, right parentheses, returns a String containing the exception class name and a message indicating the cause of the exception. Row 3. Return Value: void. Method Name And Exception List: print Stack Trace, left parentheses, right parentheses, prints the line number of the code that caused the exception, along with the sequence of method calls leading up to the exception.

Back to Table

Program code. The code contains the following keywords: import, public, class, static, void, String, try, while, int, catch. Line 1: Forward slash. Asterisk. Reading a Text File. Line 2, indented once: Anderson, comma, Franceschi. Line 3: Asterisk. Forward slash. Line 4: blank. Line 5: import java dot i o dot File, semicolon. Line 6: import java dot i o dot File Not Found Exception, semicolon. Line 7: import java dot util dot Scanner, semicolon. Line 8: blank. Line 9: public class Echo File Data. Line 10: left brace. Line 11, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 12, indented once: left brace. Line 13, indented twice: try. Line 14, indented twice: left brace. Line 15, indented thrice: File input File, equals, new File, left parentheses, double quotes, data dot t x t, double quotes, right parentheses, semicolon. Line 16, indented thrice: Scanner file, equals, new Scanner, left parentheses, input File, right parentheses, semicolon. Line 17: blank. Line 18, indented thrice: while, left parentheses, file dot has Next Int, left parentheses, right parentheses, right parentheses. Line 19, indented thrice: left brace. Line 20, indented 4 times: int number, equals, file dot next Int, left parentheses, right parentheses, semicolon. Line 21, indented 4 times: System dot out dot print l n, left parentheses, number, right parentheses, semicolon. Line 22, indented thrice: right brace. Line 23, indented twice: right brace. Line 24, indented twice: catch, left parentheses, File Not Found Exception f n f e, right parentheses. Line 25, indented twice: left brace. Line 26, indented thrice: System dot out dot print l n, left parentheses, double quotes, Message, colon, blank space, double quotes, plus, f n f e dot get Message, left parentheses, right parentheses, right parentheses, semicolon. Line 27, indented thrice: System dot out dot print l n, left parentheses, double quotes, backslash, n, to String, left parentheses, right parentheses, colon, blank space, double quotes, plus, f n f e, plus, double quotes, backslash, n, double quotes, right parentheses, semicolon. Line 28, indented thrice: f n f e dot print Stack Trace, left parentheses, right parentheses, semicolon. Line 29, indented twice: right brace. Line 30, indented once: right brace. Line 31: right brace.

Back to Example

The columns of the first table are labeled File Constructor and Exceptions Thrown. The row entry is as follows. Row 1. File Constructor: File, left parentheses, String path name, right parentheses, constructs a File object with the path name file name so that the file name is platform independent. Exceptions Thrown: Null Pointer Exception. The columns of the second table are labeled Scanner Constructor Methods and Exceptions Thrown. The row entry is as follows. Row 1. Scanner Constructor and Methods: Scanner, left parentheses, File file, right parentheses, constructs a Scanner object for reading from a file. Exceptions Thrown: File Not Found Exception. The columns of the third table are labeled Return Value, Method Name and Argument List, and Exceptions Thrown. The row entries are as follows. Row 1. Return Value: boolean. Method Name and Argument List: has Next, left parentheses, right parentheses, returns true if there is another token in the input stream. Return Value: boolean. Method Name and Argument List: has Next Line, left parentheses, right parentheses, returns true if there is another line or line separator in the input stream. Exceptions Thrown: Both methods throw an Illegal State Exception. Row 2. Return Value: boolean. Method Name and Argument List: has Next Int, left parentheses, right parentheses. Return Value: boolean. Method Name and Argument List: has Next Double, left parentheses, right parentheses. Return Value: boolean. Method Name and

Argument List: has Next Float, left parentheses, right parentheses, returns true if there is another token in the input stream of the specified data type. Exceptions Thrown: All these methods throw an Illegal State Exception. Row 3. Return Value: String. Method Name and Argument List: next, left parentheses, right parentheses, returns the next token in the input stream as a String. Return Value: String. Method Name and Argument List: next Line, left parentheses, right parentheses, returns the remainder of the line as a String. Positions the pointer to the next line. Exceptions Thrown: Both methods throw No Such Element Exception, Illegal State Exception. Row 4. Return Value: int. Method Name and Argument List: next Int, left parentheses, right parentheses. Return Value: double. Method Name and Argument List: next Double, left parentheses, right parentheses. Return Value: float. Method Name and Argument List: next Float, left parentheses, right parentheses, returns the next token in the input stream as the specified data type. Exceptions Thrown: All these methods throw Input Mismatch Exception, No Such Element Exception, Illegal State Exception. Return Value: void. Method Name and Argument List: close, left parentheses, right parentheses, releases the resources associated with an open input stream. Exceptions Thrown: None.

The table has 3 columns labeled Operation, If the File Exists, If the File Does Not Exist. The row entries are as follows. Row 1. Operation: write. If the File Exists: the current contents of the file are deleted, and writing starts at the beginning of the file. If the file Does Not Exist: the file is created and writing starts at the beginning of the file. Row 2. Operation: append. If the File Exists: data is added to the end of the file, keeping the existing contents. If the File Does Not Exist: the file is created and writing starts at the beginning of the file.

Back to Table

The table is titled, Classes, Constructors, and Methods for Writing to a Text File. The table has 3 columns labeled Class, Constructors, and Exceptions Thrown. The row entries are as follows. Row 1. Class: File Writer. Constructors: File Writer, left parentheses, String file name, comma, boolean mode, right parentheses, constructs a File Writer object from a String representing the name of a file; if mode is false, we will write to the file; if mode is true, we will append to the file. Exceptions thrown: I O Exception. Class: Print Writer. Constructors: Print Writer, left parentheses, Writer w r, right parentheses, constructs a Print Writer object from teh Writer object w r. Exceptions thrown: None. The method A P I's are as follows. Row 3. Class: Print Writer. Constructors: void print, left parentheses, int i, right parentheses, void print, left parentheses, double d, right parentheses, void print, left parentheses, char c, right parentheses, void print, left parentheses, boolean b, right parentheses, and so on, upto, void print l n, left parentheses, int i, right parentheses, void print l n, left parentheses, double d, right parentheses, and so on, writes the argument to a text file. Exceptions thrown: None. Row 4. Class: Print Writer. Constructors: void close, left parentheses, right parentheses, releases the resources associated with the Print Writer object. Exceptions thrown: None.

The constructor for the Scanner class is as follows. Row

1. Constructor: Scanner, left parentheses, String source, right parentheses, constructs a Scanner object that produces tokens from the specified String. Exceptions Thrown: None. The description of the Method A P I is as follows. Row 2. Return Value: Scanner. Method name and argument list: Use Delimiter, left parentheses, String pattern, right parentheses, sets this Scanner object's delimiters based on the specified pattern. Exceptions Thrown: None.

The table has 2 columns labeled Return Value and Method and Description. The row entries are as follows. Row 1. Return Value: long. Method and Description: count, left parentheses, right parentheses, returns the number of elements in this Stream. Row 2. Return Value: Stream. Method and Description: filter, left parentheses, Predicate, left angled bracket, question mark, super T, right angled bracket, predicate, right parentheses, returns a Stream made of the elements of this Stream that satisfy predicate. Row 3. Return Value: Optional. Method and Description: min, left parentheses, Comparator, left angled bracket, question mark, super T, right angled bracket, comparator, right parentheses, returns the minimum element of this Stream using the comparator. Row 4. Return Value: Optional. Method and Description: max, left parentheses, Comparator, left angled bracket, question mark, super T, right angled bracket, comparator, right parentheses, returns the maximum element of this Stream using the comparator. Row 5. Return Value: Double Stream. Method and Description: map To Double, left parentheses, To Double Function, left angled bracket, question mark, super T, right angled bracket, mapper, right parentheses, returns a Double Stream made up of the elements resulting from applying mapper to the Stream elements; map To Int and map To Long are similar methods.

Back to Table

The table has 2 columns labeled Interface and Abstract Method. The row entries are as follows. Row 1. Interface: Predicate. Abstract Method: boolean test, left parentheses, uppercase t, lowercase t, right parentheses, tests t and returns true or false. Row 2. Interface: Double Predicate. Abstract Method: boolean test, left parentheses, double d, right parentheses, tests d and returns true or false. Row 3. Interface: Comparator. Abstract Method: int compare, left parentheses, uppercase t, lowercase t 1, comma, uppercase t, lowercase t 2, right parentheses, compares lowercase t 1 and lowercase t 2 for order. Row 4. Interface: To Double Function. Abstract Method: double apply As Double, left parentheses, uppercase t, lowercase t, right parentheses, converts lowercase t to a double and returns that value.

Back to Table

Program code. The code contains the following keywords: import, public, class, implements, boolean, if, return, true, else, String, return. Line 1: Forward slash. Asterisk. Predicate testing whether a String starts with B. Line 2: Anderson, Franceschi. Line 3: Asterisk. Forward slash. Line 4: import java dot util dot function dot asterisk, semicolon. Line 5: blank. Line 6: public class Start With B Predicate, left angled bracket, uppercase t, right angled bracket, implements Predicate, left angled bracket, uppercase t, right angled bracket. Line 7: left brace. Line 8, indented once: public boolean test, left parentheses, uppercase t, lowercase t, right parentheses. Line 9, indented once: left brace. Line 10, indented twice: if, left parentheses, exclamation mark, right parentheses, t instance of String, right parentheses, right parentheses. Line 11, indented thrice: return false, semicolon. Line 12, indented twice: else. Line 13, indented twice: left brace. Line 14, indented thrice: String s, equals, left parentheses, String, right parentheses, t, semicolon. Line

15, indented thrice: return s dot char At, left parentheses, 0, right parentheses, equals, equals, single quote, uppercase b, single quote, semicolon. Line 16, indented twice: right brace. Line 17, indented once: right brace. Line 18: right brace.

The table is titled Classes, Constructors, and Methods for Writing Objects to a File. The table has 3 columns labeled Class, Constructor, and Exceptions thrown. The row entries are as follows. Row 1. Class: File Output Stream. Constructor: File Output Stream, left parentheses, String file name, comma, boolean mode, right parentheses, constructs a File Output Stream object from a String representing the name of a file; if mode is false, we will write to the file; if mode is true, we will append to the file. Exceptions thrown: File Not Found Exception. Row 2. Class: Object Output Stream. Constructor: Object Output Stream, left parentheses, Output Stream out, right parentheses, creates an Object Output Stream that writes to the Output Stream out. Exceptions thrown: I O Exception. The description of the Method A P I is as follows. Class: Object Output Stream. Constructor: void write Object, left parentheses, Object o, right parentheses, writes the object argument to a file. That object must be an instance of a class that implements the Serializable interface. Otherwise, a run-time exception will be generated. Exceptions thrown: I O Exception, Not Serializable Exception, Invalid Class Exception.

The table is titled Classes, Constructors, and Methods for Reading Objects from a File. The table has 3 columns labeled Class, Constructors, and Exceptions thrown. The row entries are as follows. Row 1. Class: File Input Stream. Constructors: File Input Stream, left parentheses, String file name, right parentheses, constucts a File Input Stream object from a String representing the name of a file. Exceptions thrown: File Not Found Exception. Row 2. Class: Object Input Stream. Constructors: Object Input Stream, left parentheses, Input Stream i n, right parentheses, constructs an Object Input Stream from the Input Stream i n. Exceptions thrown: I O Exception. The Method A P I is as follows. Row 3. Class: Object Input Stream. Constructors: Object read Object, left parentheses, right parentheses, reads the next object and returns it. The object must be an instance of a class that implements the Serializable interface. When the end of the file is reached, an E O F Exception is thrown.

Exceptions thrown: I O Exception, Class Not Found Exception, E O F Exception.

The table is titled Methods of the Integer Linked List class. The table has 2 columns labeled Return Value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: insert, left parentheses, int value, right parentheses, inserts value at the beginning of the list. Row 2. Return value: boolean. Method name and argument list: delete, left parentheses, int value, right parentheses, removes the first item on the list that is equal to value and returns true. If there is no such item on the list, the method returns false. Row 3. Return value: String. Method name and argument list: to String, left parentheses, right parentheses, returns a String representation of the list.

The table is titled, Constructor and Methods of the abstract Shell Linked List Class. The columns of the first row are labeled Class, Constructor and argument list. The columns of the remaining 3 rows are labeled Return Value and Method name and argument list. The row entries are as follows. Row 1. Class: Shell Linked List. Constructor and argument list: Shell Linked List, left parentheses, right parentheses, constructs an empty list. Row 2. Return value: int. Method name and argument list: get Number Of

Items, left parentheses, right parentheses, returns the number of items in the list. Row 3. Return value: boolean. Method name and argument list: is Empty, left parentheses, right parentheses, returns true if the list contains 0 items, false otherwise. Row 4. Return value: String. Method name and argument list: to String, left parentheses, right parentheses, returns the contents of every node in the list.

Back to Example

The table is titled Methods of the Player Linked List Class. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: insert, left parentheses, Player p, right parentheses, inserts Player p at the beginning of the list. Row 2. Return value: Player. Method name and argument list: delete, left parentheses, int search I D, right parentheses, returns and removes the first Player in the list with an I D equal to search I D. If there is no such Player in the list, the method throws a Data Structure Exception. Row 3. Return value: Player. Method name and argument list: peek, left parentheses, int search I D, right parentheses, returns the first Player on the list whose I D is equal to search I D. If there is no such Player in the list, the method throws a Data Structure Exception.

A table titled, Constructors and Methods of the Node Class. The first table summmarizes the Constructors of the Node Class. The table has 2 columns labeled Class and Constructor and argument list. The row entries are as follows. Row 1. Class: Node. Constructor and argument list: Node, left parentheses, int data, right parentheses, constructs a new Node object whose data instance variable is data. The pointer to the next node is set to the value null. Row 2. Class: Node. Constructor and argument list: Node, left parentheses, int data, comma, Node next Node, right parentheses, constructs a new Node object whose data instance variable is data. The Node points to next Node. The second table summarizes the methods of the Node class. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: Node. Method name and argument list: set Next, left parentheses, Node next Node, right parentheses, sets the Node object reference pointed to by this Node to next Node. Row 2. Return value: Node. Method name and argument list: set Data, left parentheses, int data, right parentheses, sets the data instance variable to data. Row 3. Return value: Node. Method name and argument list: get Next, left parentheses, right parentheses, returns an object reference to the Node pointed to by this Node. Row 4. Return value: int. Method name and argument list: get Data, left parentheses, right parentheses, returns the data stored in this Node.

The table is titled, Methods of the Recursive Linked List Class. The table has 2 columns labeled Return Value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: insert, left parentheses, T item, right parentheses, inserts item at the beginning of the list. Row 2. Return value: boolean. Method name and argument list: delete, left parentheses, T item, right parentheses, removes the first object of the list that matches item and returns true. If there is no such object in the list, the method returns false.

The table has 2 columns labelled Order of Magnitude and Number of Statements Executed. The column labelled Number of Statements Executed is subdivided into 4 columns which are labelled n equals 10, n equals 20, n equals 1000 and n equals 1 million. The row entries are as follows. Row 1. Order of Magnitude: log n. Number of

Statements Executed, n equals 10: 2.23. Number of Statements Executed, n equals 20: 3.23. Number of Statements Executed, n equals 1000: Approximately 10. Number of Statements Executed, n equals 1 million: Approximately 20. Row 2. Order of Magnitude: n. Number of Statements Executed, n equals 10: 10. Number of Statements Executed, n equals 20: 20. Number of Statements Executed, n equals 1000: 1000. Number of Statements Executed, n equals 1 million: 10 to the power of 6. Row 3. Order of Magnitude: n log n. Number of Statements Executed, n equals 10: 22.3. Number of Statements Executed, n equals 20: 64.6. Number of Statements Executed, n equals 1000: Approximately 10000. Number of Statements Executed, n equals 1 million: Approximately 20 times 10 to the power of 6. Row 4. Order of Magnitude: n squared. Number of Statements Executed, n equals 10: 100. Number of Statements Executed, n equals 20: 400. Number of Statements Executed, n equals 1000: 10 to the power of 6. Number of Statements Executed, n equals 1 million: 10 to the power of 12. Row 5. Order of Magnitude: n cubed. Number of Statements Executed, n equals 10: 1000. Number of Statements Executed, n equals 20: 8000. Number of Statements Executed, n equals 1000: 10 to the power of 9. Number of Statements Executed, n equals 1 million: 10 to the power of 18. Row 6. Order of Magnitude: 2 to the power of n. Number of Statements Executed, n equals 10: 1024. Number of Statements Executed, n equals 20: Approximately 10 to the power of 6. Number of

Statements Executed, n equals 1000: Approximately 10 to the power of 300. Number of Statements Executed, n equals 1 million: Approximately 10 to the power of 3000000.

Back to Table

The table has 3 columns labelled f, left parentheses, n, right parentheses, Dominant Term, and Big Oh. The row entries are as follows. Row 1. f, left parentheses, n, right parentheses: 2 asterisk n plus 19. Dominant Term: 2 asterisk n. Big Oh: O, left parentheses, n, right parentheses. Row 2. f, left parentheses, n, right parentheses: 3 asterisk n squared plus 6 asterisk n plus 12. Dominant Term: 3 asterisk n squared. Big Oh: O, left parentheses, n squared, right parentheses. Row 3. f, left parentheses, n, right parentheses: n cubed plus 9 asterisk n squared plus 5 asterisk n plus 2. Dominant Term: n cubed. Big Oh: O, left parentheses, n cubed, right parentheses. Row 4. f, left parentheses, n, right parentheses: 3 asterisk 2 to the power of n plus 5 asterisk n cubed plus 3 asterisk n plus 7. Dominant Term: 3 asterisk 2 to the power of n. Big Oh: O, left parentheses, 2 to the power of n, right parentheses. Row 5. f, left parentheses, n, right parentheses: n plus 7 asterisk log n. Dominant Term: n. Big Oh: O, left parentheses, n, right parentheses. Row 6. f, left parentheses, n, right parentheses: 2 asterisk n asterisk log n plus 8 asterisk n plus log n plus 8. Dominant Term: 2 asterisk n asterisk log n. Big Oh: O, left parentheses, n asterisk log n, right parentheses. Row 7. f, left parentheses, n, right parentheses: 3 asterisk log n plus 35. Dominant Term: 3 asterisk log n. Big Oh: O, left parentheses, log n, right parentheses.

Back to Table

Program code. The code contains the following keywords: public, static, int, while, return. Line 1: public static int add Elements, left parentheses, int, left square bracket, right square bracket, a r r, right parentheses. Line 2: left brace. Line 3, indented once: int sum, equals, 0, semicolon. 2 forward slashes, left parentheses, 1, right parentheses. Line 4, indented once: int i equals 0, semicolon. 2 forward slashes, left parentheses, 2, right parentheses. Line 5, indented twice: while, left parentheses, i less than a r r dot length, right parentheses. 2 forward slashes, left parentheses, 3, right parentheses. Line 6, indented twice: left brace. Line 7, indented thrice: sum, plus, equals, a r r, left parentheses, i, right parentheses, semicolon. 2 forward slashes, left parentheses, 4, right parentheses. Line 8, indented thrice: i plus, plus, semicolon. 2 forward slashes, left parentheses, 5, right parentheses. Line 9, indented twice: right brace. Line 10, indented once: return sum, semicolon. 2 forward slashes, left parentheses, 6, right parentheses. Line 11: right brace.

Back to Example

Program code. The code contains the following keywords:

public, static, int, for, if, return. Line 1: public static int calculate Maximum, left parentheses, int, left square bracket, right square bracket, left square bracket, right square bracket, a r r, right parentheses. Line 2: left brace. Line 3, indented once: int maximum, equals, a r r, left square bracket, 0, right square bracket, left square bracket, 0, right square bracket, semicolon. 2 forward slashes, left parentheses, 1, right parentheses. Line 4, indented once: for, left parentheses, int i equals 0, semicolon, i less than a r r dot length, semicolon, i plus, plus, right parentheses. 2 forward slashes, left parentheses, 2, right parentheses. Line 5, indented once: left brace. Line 6, indented twice: for, left parentheses, int j equals 0, semicolon, j less than a r r, left square bracket, i, right square bracket, dot, length, semicolon, j plus, plus, right parentheses. 2 forward slashes, left parentheses, 3, right parentheses. Line 7, indented twice: left brace. Line 8, indented thrice: if, left parentheses, maximum, less than, a r r, left square bracket, i, right square bracket, left square bracket, j, right square bracket, right parentheses. 2 forward slashes, left parentheses, 4, right parentheses. Line 9, indented 4 times: maximum, equals, a r r, left square bracket, i, right square bracket, left square bracket, j, right square bracket, semicolon. 2 forward slashes, left parentheses, 5, right parentheses. Line 10, indented twice: right brace. Line 11, indented once: right brace. Line 12, indented once: return maximum, semicolon. 2 forward slashes, left parentheses, 6, right parentheses. Line 13: right brace.

Back to Example

Program code. The code contains the following keywords: public, static, int, for, if, return. Line 1: public static int sequential Search, left parentheses, int, left square bracket, right square bracket, array, comma, int key, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int i equals 0, semicolon, i less than array dot length, semicolon, i plus, plus, right parenthess. 2 forward slashes, left parentheses, 1, right parentheses. Line 4, indented twice: if, left parentheses, array, left square bracket, i, right square bracket, 2 equals sign, key, right parentheses. 2 forward slashes, left parentheses, 2, right parentheses. Line 5, indented thrice: return i, semicolon. 2 forward slashes, left parentheses, 3, right parentheses. Line 6, indented once: return negative 1, semicolon. 2 forward slashes, left parentheses, 4, right parentheses. Line 7: right brace.

Back to Example

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int power Of 2 A, left parentheses, int n, right parentheses. 2 forward slashes, n greater than or equal to 0. Line 2: left brace. Line 3, indented once: if, left parentheses, n, 2 equals sign, 0, right parentheses. Line 4, indented twice: return 1, semicolon. Line 5, indented once: else. Line 6, indented twice: return 2 asterisk power Of 2 A, left parentheses, n minus 1, right parentheses, semicolon.

Line 7: right brace.

Back to Example

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int power Of 2 B, left parentheses, int n, right parentheses. 2 forward slashes, n greater than or equal to 0. Line 2: left brace. Line 3, indented once: if, left parentheses, n, 2 equals sign, 0, right parentheses. Line 4, indented twice: return 1, semicolon. Line 5, indented once: else. Line 6, indented twice: return power Of 2 B, left parentheses, n minus 1, right parentheses, plus, power Of 2 B, left parentheses, n minus 1, right parentheses, semicolon. Line 7: right.

Back to Example

Line 1: 2 forward slashes. 1. 5 asterisks. student writes this method. Line 2: Forward slash comma 2 asterisks. Sorts a r r in ascending order using the selection sort algorithm. Line 3: Asterisk. Adds a counter to count the number of statement executions. Line 4: Asterisk. Forward slash. Line 5: public int selection Sort comma left parentheses comma right parentheses. Line 6: Left brace. Line 7: 2 forward slashes. Note, colon, To count the number of statement executions comma use a counter. Line 8: 2 forward slashes. The variable counter has been declared and initialized for you. Line 9: 2 forward slashes. at the beginning of this method. Line 10: 2 forward slashes. Inside the body of the inner loop comma increment the counter. Line 11: 2 forward slashes. Replace the return statement so that this method returns the value of. Line 12: 2 forward slashes. the counter. To slow down or accelerate the animation comma modify the. Line 13: 2 forward slashes. argument of Pause dot wait in the handle method of the Array Animation Timer inner class. Line 14: int counter equals 0, semicolon. Line 15: int temp comma index Of Max, semicolon. Line 16: for left parentheses int i equals 0, semicolon. i less than a r r dot length minus 1, semicolon. i plus, plus right parentheses. Line 17: Left brace. Line 18: 2 forward slashes. find index of largest value in the subarray. Line 19: index Of Max equals 0, semicolon. Line 20: animate left parentheses i comma 0 comma 0 comma counter right parentheses, semicolon. Line 21: for left parentheses int j equals 1, semicolon. j less than a r r dot length minus i, semicolon. j plus, plus right parentheses. Line 22: Left brace. Line 23: if left parentheses a r r left square bracket j right square bracket greater than a r r left square bracket index Of Max right square bracket right parentheses. Line 24: index Of Max equals j, semicolon. Line 25: animate left parentheses i comma j comma index Of Max comma counter right parentheses, semicolon. Line 26: Right brace. Line 27: 2 forward slashes. swap a r r left square bracket index Of Max right square bracket and a r r left square bracket a r r dot length minus i minus 1 right square bracket. Line 28: temp equals a r r left square bracket index Of Max right square bracket , semicolon.

Line 29: a r r left square bracket index Of Max right square bracket equals a r r left square bracket a r r dot length minus i minus 1 right square bracket, semicolon. Line 30: a r r left square bracket a r r dot length minus i minus 1 right square bracket equals temp, semicolon. Line 31: Right brace. Line 32: animate left parentheses a r r dot length minus 1 comma 0 comma 0 comma counter right parentheses, semicolon. Line 33: return 0, semicolon. Line 34: Right brace. 2 forward slashes. end of selection Sort.

Forward slash. Line 223: public static int partition, left parentheses, int left square bracket, right square bracket a r r, int start, int end, right parentheses. Line 224: Left brace. Line 225: int j equals start, semicolon. Line 226: int pivot equals a r r left square bracket start right square bracket, semicolon. Line 227: for, left parentheses, int i equals start plus 1, semicolon. i less than or equal to end, semicolon. i, plus, plus, right parentheses. Line 228: Left brace. Line 229: count, plus, plus, semicolon. Line 230: if, left parentheses, a r r left square bracket i right square bracket less than pivot, right parentheses. Line 231: Left brace. Line 232: j, plus, plus, semicolon. Line 233: swap, left parentheses, a r r, i, j, right parentheses, semicolon. Line 234: Right brace. Line 235: Right brace. Line 236: swap, left parentheses, a r r, start, j, right parentheses, semicolon. Line 237: return j, semicolon. Line 238: Right brace. Line 239: blank. Line 240: Forward slash. Asterisk. Asterisk. Line 241: asterisk swap method, colon, swaps the elements of a r r. Line 242: asterisk at index i and index j. Line 243: asterisk at symbol, param a r r, an array of ints. Line 244: asterisk at symbol, param i an int, a valid index of a r r. Line 245: asterisk at symbol, param j an int, a valid index of a r r. Line 246: Asterisk. Forward slash. Line 247: public static void swap, left parentheses, int left square bracket, right square bracket a r r, int i, int j , right parentheses. Line 248: Left brace. Line 249: int temp equals a r r left square bracket i right square bracket, semicolon. Line 250: a r r left square bracket i right square bracket equals a r r left square bracket j right square bracket , semicolon. Line 251: a r r left square bracket j right square bracket equals temp, semicolon. Line 252: Right brace. Line 253: Right brace.

Back to Example

The table has 4 columns labeled Algorithm, Starting Array, Comparisons, left parentheses, simulation, right parentheses, and For n equals 1024. The row entries are as follows. Row 1. Algorithm: Insertion sort. Starting Array: Unsorted. Comparisons, left parentheses, simulation, right parentheses: 259873. For n equals 1024: About n asterisk, left parentheses, n minus 1, right parentheses, forward slash, 4. Row 2. Algorithm: Insertion sort. Starting Array: Sorted. Comparisons, left parentheses, simulation, right parentheses: 1023. For n equals 1024: n minus 1. Row 3. Algorithm: Merge sort. Starting Array: Unsorted. Comparisons, left parentheses, simulation, right parentheses: 8917. For n equals 1024: About n asterisk, log n. Row 4. Algorithm: Merge sort. Starting Array: Sorted. Comparisons, left parentheses, simulation, right parentheses: 5120. For n equals 1024: About n asterisk log n forward slash 2. Row 5. Algorithm: Quick sort. Starting Array: Unsorted. Comparisons, left parentheses, simulation, right parentheses: 10332. For n equals 1024: About n asterisk log n. Row 6. Algorithm: Quick sort. Starting Array: Sorted. Comparisons, left parentheses, simulation, right parentheses: 523776. For n equals 1024: n asterisk, left parentheses, n minus 1, right parentheses, forward slash, 2.

H T M L code for a simple web page. Program code. In the code, the words in the variable names are merged. Line 1: Left angle bracket, h t m l, right angle bracket. Line 2, indented once: left angle bracket, head, right angle bracket. Line 3, indented twice: Left angle bracket, title, right angle bracket, My web page, left angle bracket, forward slash, title, right angle bracket. Line 4, indented once: Left angle bracket, forward slash, head, right angle bracket. Line 5, indented once: Left angle bracket, body, right angle bracket. Line 6, indented twice: Left angle bracket, p, right angle bracket, Web tools, left angle bracket forward slash, p, right angle bracket. Line 7, indented twice: Left angle bracket, o l, right angle bracket. Line 8, indented 3 times: Left angle bracket, l i, right angle bracket, H t m l, left angle bracket, forward slash, l i, right angle bracket. Line 9, indented 3 times: Left angle bracket, l i, right angle bracket, C s s, left angle bracket, forward slash, l i, right angle bracket. Line 10, indented 3 times: Left angle bracket, l i, right angle bracket, JavaScript, left angle bracket, forward slash, l i, right angle bracket. Line 11, indented twice: Left angle bracket, forward slash, o l, right angle bracket. Line 12, indented once: Left angle bracket, forward slash, body, right angle bracket. Line 13: Left angle bracket, forward slash, h t m l, right angle bracket.

Back to Example

A table detailing tree terminology. The table has 8 rows and 2 columns. It has the following column headings. Term. Description. The row details in the table are the following. Row 1: Term, Leaf; Description, A node with no child. Row 2: Term, Interior node; Description, A node with at least one child. Row 3: Term, Siblings; Description, Two (or more) nodes with the same parent. Row 4: Term, Degree of a node; Description, The number of children of a node. Row 5: Term, Depth of a node; Description, The number of edges on the path from the root to the node. Row 6: Term, Level of a node; Description, The number of edges on the path from the root to the node. Row 7: Term, Height of a node; Description, The largest number of edges on a path from a node to a leaf. Row 8: Term, Height of the tree; Description, The height of the root.

Back to Table

A table detailing number of nodes per level in a full binary tree. The table has 8 rows and 2 columns. It has the following column headings. Level. Number of Nodes. The row details in the table are the following. Row 1: Level, 0; Number of Nodes, 1 equals 2 to the power of 0. Row 2: Level, 1; Number of Nodes, 2 equals 2 to the power of 1. Row 3: Level, 2; Number of Nodes, 4 equals 2 to the power of 2. Row 4: Level, 3; Number of Nodes, 8 equals 2 to the power of 2. Row 5: Level, 4; Number of Nodes, 16 equals 2 to the power of 2. Row 6: Level, 5; Number of Nodes, 32 equals 2 to the power of 5. Row 7: Level, 6; Number of Nodes, 64 equals 2 to the power of 6. Row 8:

Level, L; Number of Nodes, 2 to the power of L.

Line 47, indented once: asterisk, at return, a String representation of the pre order. Line 48, indented once: asterisk, tab space, traversal of the Binary Tree "rooted" at n d. Line 49, indented once: asterisk, forward slash. Line 50, indented once: private, String, pre Order, left parenthesis, Integer Node, n d, right parenthesis. Line 51, indented once: Left brace. Line 52, indented twice: if, left parenthesis, n d, not equals, null, right parenthesis. Line 53, indented twice: Left brace. Line 54, indented 3 times: forward slash, forward slash, visit n d. Line 55, indented 3 times: String, result, equals, n d, dot, get Data, left parenthesis, right parenthesis, plus, open quotes, space, close quotes, semicolon. Line 56, indented 3 times: Forward slash, forward slash, visit left subtree in pre order. Line 57, indented 3 times: result, plus, equals, pre Order, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 58, indented 3 times: forward slash, forward slash, visit right subtree in pre order. Line 59, indented 3 times: result, plus, equals, pre Order, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 60, indented 3 times: return, result, semicolon. Line 61, indented twice: Right brace. Line 62, indented twice: else. Line 63, indented once: return, open quotes, slow quotes, semicolon. Line 64, indented once: Right brace. Line 65: Blank. Line 66, indented once: Forward slash, asterisk, asterisk, in Order method. Line 67, indented once: asterisk, at, return a String representation of the in order. Line 68, indented once: asterisk, traversal of this Binary Tree. Line 69, indented once: asterisk, forward slash. Line 70, indented once: public, String, in Order, left parenthesis, right parenthesis. Line 71, indented once: Left brace. Line 72, indented twice: return, in Order, left parenthesis, root, right parenthesis, semicolon. Line 73, indented once: right brace. Line 74: Blank. Line 75, indented once: Forward slash, asterisk, asterisk, in Order recursive method. Line 76, indented once: asterisk, @, param, n d an Integer Node reference. Line 77, indented once: asterisk, at, return a String representation of the in order. Line 78, indented once: asterisk, traversal of the Binary Tree "rooted" at n d. Line 79, indented once: asterisk, forward slash. Line 80, indented once: private, String, in Order, left parenthesis, Integer Node, n d, right parenthesis. Line 81, indented once: Left brace. Line 82, indented twice: if, left parenthesis, n d, not equals, null, right parenthesis. Line 83, indented twice: Left brace. Line 84, indented 3 times: forward slash, forward slash, visit left subtree in order. Line 85, indented 3 times: String, result, equals, in Order, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 86, indented 3 times: forward slash, forward slash, visit n d. Line 87, indented 3 times: result, plus, equals, n d, dot, get Data, left parenthesis, right parenthesis, plus, open quotes, space, close quotes, semicolon. Line 88, indented 3 times: forward slash, forward slash, visit right subtree in order. Line 89, indented 3 times: result, plus, equals in Order, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 90, indented 3 times: return, result, semicolon. Line 91, indented twice: Right brace. Line 92, indented twice: else. Line 93, indented 3 times: return, open quotes, close quotes, semicolon. Line 94, indented once: Right brace. Line 95: Blank. Line 96, indented once: Forward slash, asterisk, asterisk, post Order method. Line 97, indented once: Asterisk, at, return, a String representation of the post order. Line 98, indented once: asterisk, traversal of this Binary Tree. Line 99, indented once: Asterisk, forward slash. Line 100, indented once: public, String, post Order, left parenthesis, right parenthesis. Line 101, indented once: Left brace. Line 102, indented twice: return post Order, left parenthesis, root, right parenthesis, semicolon. Line 103, indented once: right brace. Line 104: Blank. Line 105, indented once: Forward slash, asterisk, asterisk, post Order recursive method. Line 106, indented once: Asterisk, at, param, n d, an Integer Node reference. Line 107, indented once: Asterisk, at, return, a String representation of the post order. Line 108, indented once: asterisk, traversal of the Binary Tree "rooted" at n d. Line 109, indented once: Asterisk, forward slash. Line 110, indented once: private, String, post Order, left parenthesis, Integer Node, n d, right parenthesis. Line 111, indented once: Left brace. Line 112, indented twice: if, left parenthesis, n d, not equals, null, right parenthesis. Line 113, indented twice: Left brace. Line 114, indented 3 times: forward slash, forward slash, visit left subtree in order. Line 115, indented 3 times: String, result, equals, post Order, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 116, indented 3 times: Forward slash, forward slash, visit right subtree in order. Line 117, indented 3 times: result, plus, equals, post Order, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 118, indented 3 times: Forward slash, forward slash, visit n d. Line 119, indented 3 times: result, plus, equals, n d, dot, get Data, left parenthesis, right parenthesis, plus, open quotes, space, close quotes, semicolon. Line 120, indented 3 times: return, result, semicolon. Line 121, indented twice: Right brace. Line 122, indented once: else. Line 123, indented once: return, open quotes, close quotes, semicolon. Line 124, indented once: Right brace. Line 125: Right brace.

Back to Example

A table detailing tree traversal strategies and results for the binary tree in figure 15.10. The table has 4 rows and 3 columns. It has the following column headings. Traversal. Strategy. Result. The row details are the following. Row 1: Traversal, Level Order; Strategy, Visit one level at a time, left to right; Result, 33, 20, 21, 34, 87, 84, 17, 25, 44. Row 2: Traversal, Pre Order; Strategy, Visit node the first time we see it; Result, 33, 20, 34, 17, 87, 25, 44, 21, 84. Row 3: Traversal, In Order; Strategy, Visit node the second time we see it; Result, 34, 17, 20, 25, 87, 44, 33, 21, 84. Row 4: Traversal, Post Order; Strategy, Visit node the third or last time we see it; Result, 17, 34, 25, 44, 87, 20, 84, 21, 33.

indented once: Forward slash, asterisk, asterisk, search method. Line 53, indented once: asterisk, at, param, value an i n t value to search for in this B S T. Line 54, indented once: at, return true if value is found, comma, false otherwise. Line 55, indented once: asterisk, forward slash. Line 56, indented once: public, boolean, search, left parenthesis, i n t, value, right parenthesis. Line 57, indented once: Left brace. Line 58, indented twice: return, search, left parenthesis, value, comma, root, right parenthesis, semicolon. Line 59, indented once: Right brace. Line 60: Blank. Line 61, indented once: Forward slash, asterisk, asterisk, search recursive method. Line 62, indented once: asterisk, at, param, value an i n t to search for in the B S T "rooted" at n d. Line 63, indented once: asterisk, at, param n d an Integer Node reference. Line 64, indented once: asterisk, at, return a String represeboolean, comma, true if value was found. Line 65, indented once: asterisk in the B S T "rooted" at n d, comma, false otherwise. Line 66, indented once: Asterisk, forward slash. Line 67, indented once: private, boolean, search, left parenthesis, i n t, value, comma, Integer Node, n d, right parenthesis. Line 68, indented once: Left brace. Line 69, indented once: Left brace. Line 69, indented twice: if, left parenthesis, n d, equals, equals, null, right parenthesis, forward slash, forward slash, base case, comma, empty subtree. Line 70, indented 3 times: return, false, semicolon. Line 71, indented twice: else. Line 72, indented twice: Left brace. Line 73, indented 3 times: if, left parenthesis, n d, dot, get Data, left parenthesis, right parenthesis, equals, equals, value, right parenthesis, forward slash, forward slash, found value. Line 74, indented 4 times: return, true, semicolon. Line 75, indented 3 times: else, if, left parenthesis, n d, dot, get Data, left parenthesis, right parenthesis, greater than, value, right parenthesis, forward slash, forward slash, look left. Line 76, indented 4 times: return, search, left parenthesis, value, comma, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 77, indented 3 times: else, forward slash, forward slash, look right. Line 78, indented 4 times: return, search, left parenthesis, value, comma, n d, dot, get Right, left parenthesis, right parenthesis, semicolon. Line 79, indented twice: Right brace. Line 80, indented once: Right brace. Line 81: Blank. Line 82, indented once: Forward slash, asterisk, asterisk, max Value method. Line 83, indented once: Asterisk, at, param, n d an Integer Node reference, comma, not null. Line 84, indented once: Asterisk, at, return the largest value in the B S T "rooted" at n d. Line 85, indented once: Asterisk, forward slash. Line 86, indented once: private, i n t, max Value, left parenthesis, Integer Node, n d, right parenthesis. Line 87, indented once: Left brace. Line 88, indented twice: Integer Node, temp, equals, n d, semicolon. Line 89, indented twice: while, left parenthesis, temp, dot, get Right, left parenthesis, right parenthesis, exclamation mark, equals, null, right parenthesis. Line 90, indented 3 times: temp, equals, temp, dot, get Right, left parenthesis, right parenthesis, semicolon. Line 91, indented twice: return, temp, dot, get Data, left parenthesis, right parenthesis, semicolon. Line 92, indented once: Right brace. Line 93: Blank. Line 94, indented once: Forward slash, asterisk, asterisk, delete method. Line 95, indented once: Asterisk, at, param, value an i n t value to delete in this B S T. Line 96, indented once: Asterisk, forward slash. Line 97, indented once: public, void, delete, left parenthesis, i n t, value, right parenthesis. Line 98, indented once: Left brace. Line 99, indented twice: root, equals, delete, left parenthesis, value, comma, root, right parenthesis, semicolon. Line 100, indented once: Right brace. Line 101: Line 102, indented once: Forward slash, asterisk, asterisk, delete recursive method. Line 103, indented once: Asterisk, at, param, value an i n t to delete from in the B S T "rooted" at n d. Line 104, indented once: Asterisk, at, param, n d an Integer Node reference. Line 105, indented once: Asterisk, at, return an Integer Node. Line 106, indented once: Asterisk, forward slash. Line 107, indented once: private, Integer Node, delete, left parenthesis, i n t, value, comma, Integer Node, n d, right parenthesis. Line 108, indented once: Left brace. Line 109, indented twice: if, left parenthesis, n d, equals, equals, null, right parenthesis, forward slash, forward slash, base case, comma, empty subtree. Line 110, indented 3 times: return, null, semicolon. Line 111, indented twice: else, if, left parenthesis, n d, dot, get Data, left parenthesis, right parenthesis, equals, equals, value, right parenthesis, forward slash, forward slash, found value. Line 112, indented twice: Left brace. Line 113, indented 3 times: if, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, equals, equals, null, right parenthesis, forward slash, forward slash, left child only or leaf. Line 114, indented 4 times: n d, equals, n d, dot, get Left, left parenthesis, right parenthesis, semicolon. Line 115, indented 3 times: else, if, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, equals, equals, null, right parenthesis, forward slash, forward slash, right child only. Line 116, indented 4 times: n d, equals, n d, dot, get Right, left parenthesis, right parenthesis, semicolon. Line 117, indented 3 times: else, forward slash, forward slash, 2 children. Line 118, indented 3 times: Left brace. Line 119, indented 4 times: i n t, replacement, equals, max Value, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 120, indented 4 times: n d, dot, set Data, left parenthesis, replacement, right parenthesis, semicolon. Line 121, indented 4 times: n d, dot, set Left, left parenthesis, delete, left parenthesis, replacement, comma, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 122, indented 3 times: Right brace. Line 123, indented twice: Right brace. Line 124, indented twice: else, if, left parenthesis, n d, dot, get Data, left parenthesis, right parenthesis, greater than, value, right parenthesis, forward slash, forward slash, delete in left subtree. Line 125, indented 3 times: n d, dot, set Left, left parenthesis, delete, left parenthesis, value, comma, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, right parenthesis, semicolon. Line 126, indented twice: else, forward slash, forward slash, delete in right subtree. Line 127, indented 3 times: n d, dot, set Right, left parenthesis, delete, left parenthesis, value, comma, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, right parenthesis, semicolon. Line 128: Blank. Line 129, indented twice: return, n d, semicolon. Line 130, indented once: Right brace. Line 131: Blank. Line 132, indented once: Forward slash, asterisk, asterisk, rebalance method. Line 133, indented once: asterisk, at, param, a r r an array of i n t s sorted in ascending order. Line 134, indented once: Asterisk, rebuilds this B S T with the values in a r r. Line 135, indented once: asterisk, so that this B S T is now balanced. Line 136, indented once: Asterisk, forward slash. Line 137, indented once: public, void, rebalance, left parenthesis, i n t, left square brace, right square brace, a r r, right parenthesis. Line 138, indented once: Left brace. Line 139, indented twice: root, equals, rebalance, left parenthesis, a r r, comma, 0, comma, a r r, dot, length, minus, 1, right parenthesis, semicolon. Line 140, indented once: Right brace. Line 141: Blank. Line 142, indented once: Forward slash, asterisk, asterisk, rebalance recursive method. Line 143, indented once: Asterisk, at, param, a r r an array of i n t s sorted in ascending order. Line 144, indented once: Asterisk, at, param, start an i n t, comma, a valid index of a r r. Line 145, indented once: Asterisk, at, param end an i n t, comma, a valid index of a r r. Line 146, indented once:

Asterisk, at, return an Integer Node, comma, the "root" of a balanced B S T. Line 147, indented once: Asterisk, made up of all the elements of a r r between start and end. Line 148, indented once: Asterisk, forward slash. Line 149, indented once: private, Integer Node, rebalance, left parenthesis, i n t, left square brace, right square brace, a r r, comma, i n t, start, comma, i n t, end, right parenthesis. Line 150, indented once: Left brace. Line 151, indented twice: if, left parenthesis, start, less than or equals, end, right parenthesis. Line 152, indented twice: Left brace. Line 153, indented 3 times: i n t, middle, equals, left parenthesis, start, plus, end, right parenthesis, forward slash, 2, semicolon. Line 154, indented 3 times: Integer Node, n d, equals, new, Integer Node, left parenthesis, a r r, left square brace, middle, right square brace, right parenthesis, semicolon. Line 155, indented 3 times: n d, dot, set Left, left parenthesis, rebalance, left parenthesis, a r r, comma, start, comma, middle, minus, 1, right parenthesis, right parenthesis, semicolon. Line 156, indented 3 times: n d, dot, set Right, left parenthesis, rebalance, left parenthesis, a r r, comma, middle, plus, 1, comma, end, right parenthesis, right parenthesis, semicolon. Line 157, indented 3 times: return, n d, semicolon. Line 158, indented twice: Right brace. Line 159, indented twice: else. Line 160, indented twice: return, null, semicolon. Line 161, indented once: Right brace. Line 162: Blank. Line 163, indented once: Forward slash, asterisk, asterisk, pre Order method. Line 164, indented once: Asterisk, at, return a String representation of the pre order. Line 165, indented once: Asterisk, traversal of this Binary Tree. Line 166, indented once: Asterisk, forward slash. Line 167, indented once: public, String, pre Order, left parenthesis, right parenthesis. Line 168, indented once: Left brace. Line 169, indented twice: return, pre Order, left parenthesis, root, right parenthesis, semicolon. Line 170, indented once: Right brace. Line 171: Blank. Line 172, indented once: Forward slash, asterisk, asterisk, pre Order recursive method. Line 173, indented once: Asterisk, at, param, n d an Integer Node reference. Line 174, indented once: Asterisk, at, return a String representation of the pre order. Line 175, indented once: Asterisk, traversal of the Binary Tree "rooted" at n d. Line 176, indented once: Asterisk, forward slash. Line 177, indented once: private, String, pre Order, left parenthesis, Integer Node, n d, right parenthesis. Line 178, indented once: Left brace. Line 179, indented twice: if, left parenthesis, n d, not equals, null, right parenthesis. Line 180, indented twice: Left brace. Line 181, indented 3 times: Forward slash, forward slash, visit n d. Line 182, indented 3 times: String, result, equals, n d, dot, get Data, left parenthesis, right parenthesis, plus, open quotes, space, close quotes, semicolon. Line 183, indented 3 times: Forward slash, forward slash, visit left subtree in pre order. Line 184, indented once: result, plus, equals, pre Order, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 185, indented 3 times: Forward slash, forward slash, visit right subtree in pre order. Line 186, indented 3 times: result, plus, equals, pre Order, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 187, indented 3 times: return, result, semicolon. Line 188, indented twice: Right brace. Line 189, indented twice: else. Line 190, indented 3 times: return, open quotes, close quotes, semicolon. Line 191, indented once: Right brace. Line 192: Blank. Line 193, indented once: Forward slash, asterisk, asterisk, in Order method. Line 194, indented once: Asterisk, at, return, a String representation of the in order. Line 195, indented once: asterisk, traversal of this Binary Tree. Line 196, indented once: Asterisk, forward slash. Line 197, indented once: public, String, in Order, left parenthesis, right parenthesis. Line 198, indented once: Left brace. Line 199, indented twice: return, in Order, left parenthesis, root, right parenthesis, semicolon. Line 200, indented once: Right brace. Line 201: Blank. Line 202, indented once: Forward slash, asterisk, asterisk, in Order recursive method. Line 203, indented once: Asterisk, at, param n d an Integer Node reference. Line 204, indented once: Asterisk, at, return, a String representation of the in order. Line 205, indented once: Asterisk, traversal of the Binary Tree "rooted" at n d. Line 206, indented once: Asterisk, forward slash. Line 207, indented once: private, String, in Order, left parenthesis, Integer Node, n d, right parenthesis. Line 208, indented once: Left brace. Line 209, indented twice: if, left parenthesis, n d, not equals, null, right parenthesis. Line 210, indented twice: Left brace. Line 211, indented 3 times: Forward slash, forward slash, visit left subtree in order. Line 212, indented 3 times: String, result, equals, in Order, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 213, indented 3 times: Forward slash, forward slash, visit n d. Line 214, indented 3 times: result, plus, equals, n d, dot, get Data, left parenthesis, right parenthesis, plus, open quotes, space, close quotes, semicolon. Line 215, indented 3 times: Forward slash, forward slash, visit right subtree in order. Line 216, indented 3 times: result, plus, equals, in Order, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 217, indented 3 times: return, result, semicolon. Line 218, indented twice: Right brace. Line 219, indented twice: else. Line 220, indented 3 times: return, open quotes, close quotes, semicolon. Line 221, indented once: Right brace. Line 222: Blank. Line 223, indented once: Forward slash, asterisk, asterisk, post Order method. Line 224, indented once: Asterisk, at, return, a String representation of the post order. Line 225, indented once: Asterisk, traversal of this Binary Tree. Line 226, indented once: Asterisk, forward slash. Line 227, indented once: public, String, post Order, left parenthesis, right parenthesis. Line 228, indented once: Left brace. Line 229, indented twice: return, post Order, left parenthesis, root, right parenthesis, semicolon. Line 230, indented once: Right brace. Line 231: Blank. Line 232, indented once: Forward slash, asterisk, asterisk, post Order recursive method. Line 233, indented once:

asterisk, at, param, n d, an Integer Node reference. Line 234, indented once: Asterisk, at, return, a String representation of the post order. Line 235, indented once: asterisk, traversal of the Binary Tree "rooted" at n d. Line 236, indented once: Asterisk, forward slash. Line 237, indented once: private, String, post Order, left parenthesis, Integer Node, n d, right parenthesis. Line 238, indented once: Left brace. Line 239, indented twice: if, left parenthesis, n d, not equals, null, right parenthesis. Line 240, indented twice: Left brace. Line 241, indented 3 times: Forward slash, forward slash, visit left subtree in order. Line 242, indented 3 times: String, result, equals, post Order, left parenthesis, n d, dot, get Left, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 243, indented 3 times: Forward slash, forward slash, visit right subtree in order. Line 244, indented 3 times: result, plus, equals, post Order, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 245, indented 3 times: Forward slash, forward slash, visit n d. Line 246, indented 3 times: result, plus, equals, n d, dot, get Data, left parenthesis, right parenthesis, plus, open quotes, plus, close quotes, semicolon. Line 247, indented 3 times: return, result, semicolon. Line 248, indented twice: Right brace. Line 249, indented twice: else. Line 250, indented 3 times: return, open quotes, close quotes, semicolon. Line 251, indented once: Right brace. Line 252, right brace.

A table detailing the recursive calls of the delete method when deleting 5. The node has one child. The table has 3 rows and 5 columns. It has the following column headings. Method call. Argument (n d). Returned node. Setting children. Line. The row details in the table are the following. Row 1: Method call, delete, left square brace, 5, comma, root, right square brace; Argument (n d), node, left parenthesis, 50, right parenthesis; Returned node, node, left square brace, 50, right square brace; Setting children, node, left parenthesis, 50, right parenthesis, set Left, left, left square brace, node, left parenthesis, 20, right parenthesis, right square brace; Line, 125. Row 2: Method call, delete, left square brace, 5, comma, node, left square brace, 20, right square brace, right square brace; Argument (n d), node, left parenthesis, 20, right parenthesis; Returned node, node, left parenthesis, 20, right parenthesis; Setting children, node, left parenthesis, 20, right parenthesis, set Left, left, left square brace, node, left parenthesis, 17, right parenthesis, right square brace; Line, 125. Row 3: Method call, delete, left square brace, 5, comma, node, left square brace, 5, right square brace, right square brace; Argument (n d), node, left square brace, 5, right square brace; Returned node, node, left square brace, 17, right square brace; Setting children, Blank; Line, Blank.

Tables detailing constructors and methods of the J Frame class. Table detailing constructors of the J Frame class. The table has 2 rows and 2 columns. It has the following column headings. Class. Constructor. The row details in the table are the following. Row 1: Class, J Frame; Constructor, J Frame, left parenthesis, right parenthesis, constructs a J Frame object, initially invisible, with no text in the title bar. Row 2: Class, J Frame; Constructor, J Frame, left parenthesis, String, title Bar Text, right parenthesis constructs a J Frame object, initially invisible, with title Bar Text displayed in the window's title bar. Table detailing methods of the J Frame class. The table has 4 rows and 2 columns. It has the following column headings. Return Value. Method name and argument list. The row details in the table are the following. Row 1: Return value, Container; Method name and argument list, get Content Pane, left parenthesis, right parenthesis returns the content pane object for this window. Row 2: Return value, void; Method name and argument list, set Default Close Operation, left parenthesis, i n t, operation, right parenthesis sets the default operation when the user closes this window, that is, when the user clicks on the X icon in the top-right corner of the window. Row 3: Return value, void; Method name and argument list, set Size, left parenthesis, i n t, width, i n t, height, right parenthesis sizes the window to the specified width and height in pixels. Row 4: Return value, void; Method name and argument list, set Visible, left parenthesis, boolean, mode, right parenthesis displays this window is mode is true, hides the window if mode is false.

Code for a shell G U I application using J Frame. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, A Shell G U I Application. Line 2: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x, dot, swing, dot, J Frame, semicolon. Line 6: import, java, dot, a w t, dot, Container, semicolon. Line 7, forward slash, forward slash, other import statements here as needed. Line 8: Blank. Line 9: public, class, Shell G U I Application, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, Container, contents, semicolon. Line 12, indented once: Forward slash, forward slash, declare other instance variables. Line 13: Blank. Line 14, indented once: Forward slash, forward slash, constructor. Line 15, indented once: public, Shell G U I Application, left parenthesis, right parenthesis. Line 16, indented once: Left brace. Line 17, indented twice: Forward slash, forward slash, call J Frame constructor with title bar text. Line 18, indented twice: super, left parenthesis, open quotes, A Shell G U I Application, close quotes, right parenthesis, semicolon. Line 19: Blank. Line 20, indented twice: Forward slash, forward slash, get container for components. Line 21, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 22: Blank. Line 23, indented twice: Forward slash, forward slash, set the layout manager. Line 24: Blank. Line 25, indented twice:

Forward slash, forward slash, instantiate G U I components and other instance variables. Line 26: Blank. Line 27, indented twice: Forward slash, forward slash, add G U I components to the content pane. Line 28: Blank. Line 29, indented twice: Forward slash, forward slash, set original size of window. Line 30, indented twice: set Size, left parenthesis, 300, comma, 200, right parenthesis, semicolon. Line 31: Blank. Line 32, indented twice: Forward slash, forward slash, make window visible. Line 33, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 34, indented once: Right brace. Line 35: Blank. Line 36, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 37, indented once: Left brace. Line 38, indented twice: Shell G U I Application basic G u i, equals, new, Shell G U I Application, left parenthesis, right parenthesis, semicolon. Line 39, indented twice: basic G u i, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 40, indented once: Right brace. Line 41: Right brace.

Back to Example

A table with details of selected G U I components and Java classes. The table has 8 rows and 3 columns. It has the following column headings. Component. Purpose. Java Class. The row details in the table are the following. Row 1: Component, Label; Purpose, Displays an image or read-only text. Labels are often paired with text fields and are used to identify the contents of the text field; Java Class, J Label. Row 2: Component, Text field; Purpose, A single-line text box for displaying information and accepting user input.; Java Class, J Text Field. Row 3: Component, Text area; Purpose, Multiple-line text field for data entry or display; Java Class, J Text Area. Row 4: Component, Password field; Purpose, Single-line text field for accepting passwords without displaying the characters typed; Java Class, J Password Field. Row 5: Component, Button; Purpose, Command button that the user clicks to signal that an operation should be performed; Java Class, J Button. Row 6: Component, Radio button; Purpose, Toggle button that the user clicks to select one option in the group. Clicking on a radio button deselects any previously selected option; Java Class, J Radio Button. Row 7: Component, Checkbox; Purpose, Toggle button that the user clicks to select 0, 1, or more options in a group; Java Class, J Check Box. Row 8: Component, Drop-down list; Purpose, Drop-down list of items that the user clicks to select one item; Java Class, J Combo Box.

Back to Table

A table detailing some useful J Component methods. Methods of the J Component class. The table has 6 rows and 2 columns. It has the following column headings. Return Value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set Visible, left parenthesis, boolean, mode, right parenthesis, makes the component visible if mode is true; hides the component if mode is false. The default is visible. Row 2: Return value, void; Method name and argument list, set Tool Tip Text, left parenthesis, String, tool Tip, right parenthesis, sets the tool tip text to tool Tip. When the mouse lingers over the component, the tool tip text will be displayed. Row 3: Return value, void; Method name and argument list, set Foreground, left parenthesis, Color, fore Color, right parenthesis, sets the foreground color of the component to fore Color. Row 4: Return value, void; Method name and argument list, set Background, left parenthesis, Color, back Color, right parenthesis, sets the background color of the component to back Color. Row 5: Return value, void; Method name and argument list, set Opaque, left parenthesis, boolean, mode, right parenthesis, sets the component's background to opaque if mode is true; sets the component's background to transparent if mode is false. If opaque, the component's background is filled with the component's background color; if transparent, the component's background is filled with the background color of the container on which it is placed. The default is transparent. Row 6: Return value, void; Method name and argument list, set Enabled, left parenthesis, boolean, mode, right parenthesis, enables the component if mode is true; disables the component if mode is false. An enabled component can respond to user input.

Back to Table

Code for a program that uses a simple G U I component, J Label. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Using J Labels to display text and images. Line 2: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import java dot a w t dot Container, semicolon. Line 6: import, java x dot swing dot J Frame, semicolon. Line 7: import, java x dot swing dot Image Icon, semicolon. Line 8: import, java x dot swing dot J Label, semicolon. Line 9: import, java dot a w t dot Flow Layout, semicolon. Line 10: import, java dot a w t dot Color, semicolon. Line 11: Blank. Line 12: public, class, Dinner, extends, J Frame. Line 13: Left brace. Line 14, indented once: private, Container, contents, semicolon. line 15, indented once: private, J Label, label Text, semicolon. Line 16, indented once: private, J Label, label Image, semicolon. Line 17: Blank. Line 18, indented once: Forward slash, forward slash, Constructor. Line 19, indented once: public, Dinner, left parenthesis, right parenthesis. Line 20, indented once: Left brace. Line 21, indented twice: super, left parenthesis, open quotes, What’s for dinner?, close quotes, right parenthesis, semicolon, tab space, forward slash, forward slash, call J Frame constructor. Line 22: Blank. Line 23, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon, tab space, forward slash, forward slash, get content pane. Line 24: Blank. Line 25, indented twice: contents dot set Layout, left parenthesis, new, Flow Layout, left parenthesis, right

parenthesis, right parenthesis, semicolon, tab space, forward slash, forward slash, set layout manager. Line 26: Blank. Line 27, indented twice: Forward slash, forward slash, use the J Label constructor with a String argument. Line 28, indented twice: label Text, equals, new, J Label, left parenthesis, open quotes, Sushi tonight?, close quotes, right parenthesis, semicolon. Line 29: Blank. Line 30, indented twice: forward slash, forward slash, set label properties. Line 31, indented twice: label Text dot set Foreground, left parenthesis, Color dot WHITE, right parenthesis, semicolon. Line
32, indented twice: label Text dot set Background, left parenthesis, Color dot BLUE, right parenthesis, semicolon. Line 33, indented twice: label Text dot set Opaque, left parenthesis, true, right parenthesis, semicolon. Line 34: Blank. Line 35, indented twice: Forward slash, forward slash, use the J Label constructor with an Image Icon argument. Line 36, indented twice: label Image, equals, new, J Label, left parenthesis, new, Image Icon, left parenthesis, open quotes, sushi dot j p g, close quotes, right parenthesis, right parenthesis, semicolon. Line 37: Blank. Line 38, indented twice: Forward slash, forward slash, set tool tip text. Line 39, indented twice: label Image dot set Tool Tip Text, left parenthesis, open quotes, photo of sushi, close quotes, right parenthesis, semicolon. Line 40: Blank. Line 41, indented twice: Forward slash, forward slash, add the two labels to the content pane. Line 42, indented twice: contents dot add, left parenthesis, label Text, right

parenthesis, semicolon. Line 43, indented twice: contents dot add, left parenthesis, label Image, right parenthesis, semicolon. Line 44: Blank. Line 45, indented twice: set Size, left parenthesis, 300, comma, 200, right parenthesis, semicolon. Line 46, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 47, indented once: Right brace. Line 48: Blank. Line 49, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 50, indented once: Left brace. Line 51, indented twice: Dinner, dinner, equals, new, Dinner, left parenthesis, right parenthesis, semicolon. Line 52, indented twice: dinner dot set Default Close Operation, left parenthesis, J Frame dot EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 53, indented once: Right brace. Line 54: Right brace.

Back to Example

A table detailing useful methods of the Container class. Methods of the Container class. The table has 3 rows and 2 columns. It has the following column headings. Return Value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set Layout, left parenthesis, Layout Manager, m g r, right parenthesis, sets the layout manager of the window to m g r. Row 2: Return value, Component; Method name and argument list, add, left parenthesis, Component, component, right parenthesis, adds the component to the container, using the rules of the layout manager. Returns the argument. Row 3: Return value, void; Method name and argument list, remove All, left parenthesis, right parenthesis, removes all components from the window.

Back to Table

A table detailing useful constructors of the J Label Class. Constructors of the J Label Class. The table has 3 rows and 2 columns. It has the following column headings. Class. Constructor. The row details in the table are the following. Row 1: Class, J Label; Constructor, J Label, left parenthesis, String, text, right parenthesis, creates a J Label object that displays the specified text. Row 2: Class, J Label; Constructor, J Label, left parenthesis, String, text, comma, i n t, alignment, right parenthesis, creates a J Label object that displays the specified text. The alignment argument specifies the alignment of the text within the label component. The alignment value can be any of the following static i n t constants from the Swing Constants interface: LEFT, CENTER, RIGHT, LEADING, or TRAILING. By default, the label text is left-adjusted. Row 3: Class, J Label; Constructor, J Label, left parenthesis, Icon, image, right parenthesis, creates a J Label object that displays the image.

Back to Table

Table detailing the get Source method inherited by Event classes. The return value is Object. The method name and argument list are the following. get Source, left parenthesis, right parenthesis, returns the object reference of the component that fired the event.

Back to Table

A table detailing component events and listeners. The table has 8 rows and 4 columns. It has the following column headings. J Component. User Interaction That Generates an Event. The Event Object Created. Listener Interface that Event Handler Should Implement. The row details in the table are the following. Row 1: J Component, J Text Field; User Interaction That Generates an Event, Pressing Enter; The Event Object Created, Action Event; Listener Interface that Event Handler Should Implement, Action Listener. Row 2: J Component, J Button; User Interaction That Generates an Event, Pressing the button; The Event Object Created, Action Event; Listener Interface that Event Handler Should Implement, Action Listener. Row 3: J Component, J Radio Button; User Interaction That Generates an Event, Selecting a radio button; The Event Object Created, Item Event; Listener Interface that Event Handler Should Implement, Item Listener. Row 4: J Component, J Check Box; User Interaction That Generates an Event, Selecting or deselecting a checkbox; The Event Object Created, Item Event; Listener Interface that Event Handler Should Implement, Item Listener. Row 5: J Component, J List; User Interaction That Generates an Event, Selecting an item; The Event Object Created, List Selection Event; Listener Interface that Event Handler Should Implement, List Selection Listener. Row 6: J Component, J Combo Box; User Interaction That Generates an Event, Selecting an item; The Event Object Created, Item Event; Listener Interface that Event Handler Should Implement, Item Listener. Row 7: J Component, Any component; User Interaction That Generates an Event, Pressing or releasing mouse buttons; The Event Object Created, Mouse Event; Listener Interface that Event Handler Should Implement, Mouse Listener. Row 8: J Component, Any component; User Interaction That Generates an Event, Moving or dragging the mouse; The Event Object Created, Mouse Event; Listener Interface that Event Handler Should Implement, Mouse Motion Listener.

Back to Table

A table detailing some add Listener methods. Add Listener Method A P Is. The table has 5 rows. The row details in the table are the following. Row 1: void, add Action Listener, left parenthesis, Action Listener, handler, right parenthesis. Row 2: void, add Item Listener, left parenthesis, Item Listener, handler, right parenthesis. Row 3: void add List Selection Listener, left parenthesis, List Selection Listener, handler, right parenthesis. Row 4: void, add Mouse Listener, left parenthesis, Mouse Listener, handler, right parenthesis. Row 5: void, add Mouse Motion Listener, left parenthesis, Mouse Motion Listener, handler, right parenthesis.

Back to Table

A table detailing useful constructors and methods of J Text Field, J Text Area, and J Password Field. Constructors and Methods of the J Text Field, J Text Area, and J Password Field classes. Constructors. The table has 6 rows and 2 columns. Class. Constructor. The row details in the table are the following. Row 1: Class, J Text Field; Constructor, J Text Field, left parenthesis, String, text, comma, i n t, num Columns, right parenthesis, constructs a text field initially filled with text, with the specified number of columns. Row 2: Class, J Text Field; Constructor, J Text Field, left parenthesis, i n t, number Columns, right parenthesis, constructs an empty text field with the specified number of columns. Row 3: Class, J Text Area; Constructor, J Text Area, left parenthesis, String, text, right parenthesis, constructs a text area initially filled with text. Row 4: Class, J Text Area; Constructor, J Text Area, left parenthesis, i n t, num Rows, comma, i n t, num Columns, right parenthesis, constructs an empty text area with the number of rows and columns specified by num Rows and num Columns. Row 5: Class, J Text Area; Constructor, J Text Area, left parenthesis, String, text, comma, i n t, num Rows, comma, i n t, num Columns, constructs a text area initially filled with text, and with the number of rows and columns specified by num Rows and num Columns. Row 6: Class, J Password Field; Constructor, J Password Field, left parenthesis, i n t, number Columns, right parenthesis, constructs an empty password field with the specified number of columns. Methods Common to J Text Field, J Text Area, and J Password Field Classes. The table has 3 rows and 2 columns. It has the following column headings. Return Value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set Editable, left parenthesis, boolean, mode, right parenthesis, sets the properties of the text component as editable or noneditable, depending on whether mode is true or false. The default is editable. Row 2: Return value, void; Method name and argument list, set Text, left parenthesis, String, new Text, right parenthesis, sets the text of the text component to new Text. Row 3: Return value, String; Method name and argument list, get Text, left parenthesis, right parenthesis, returns the text contained in the text component. Additional methods of the J Password Field class. The table has 2 rows and 2 columns, It has the following column headings. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set Echo Char, left parenthesis, char, c, right parenthesis. Row 2: Return value, char, left square brace, right square brace; Method name and argument list, get Password, left parenthesis, right parenthesis, returns the text entered in this password field as an array of chars. Note: This method is preferred over the get Text method for getting the password typed by the user.

Code for carrying out simple Math using J Button. Program code. In the code, the words in the variable names are merged. 1 Forward slash, asterisk, Simple Math Operations Using J Buttons. Line 2: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x dot swing dot asterisk, semicolon. Line 6: import java dot a w t dot asterisk, semicolon. Line 7: import, java dot a w t dot event dot asterisk, semicolon. Line 8: Blank. Line 9: public, class, Simple Math, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, Container, contents, semicolon. Line 12, indented once: private, J Label, operand Label, comma, result Label, comma, result, semicolon. Line 13, indented once: private, J Text Field, operand, semicolon. Line 14, indented once: private, J Button, square, comma, cube, semicolon. Line 15: Blank. Line 16, indented once: public Simple Math, left parenthesis, right parenthesis. Line 17, indented once: Left brace. Line 18, indented twice: super, left parenthesis, open quotes, Simple Math, close quotes, right parenthesis, semicolon. Line 19, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 20, indented twice: contents, dot, set Layout, left parenthesis, new, Flow Layout, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 21: Blank. Line 22, indented twice: operand Label, equals, new, J Label, left parenthesis, open quotes, Enter a number, close quotes, right parenthesis, semicolon, forward slash, forward slash, text field label. Line 23, indented twice: operand, equals, new, J Text Field, left parenthesis, 5, right parenthesis, semicolon, forward slash, forward slash, text field is 5 characters wide. Line 24: Blank. Line 25, indented twice: forward slash, forward slash, instantiate buttons. Line 26, indented twice: square, equals, new, J Button, left parenthesis, open quotes, Square, close quotes, right parenthesis, semicolon. Line 27, indented twice: cube, equals, new, J Button, left parenthesis, open quotes, Cube, close quotes, right parenthesis, semicolon. Line 28: Blank. Line 29, indented twice: result Label, equals, new, J Label, left parenthesis, open quotes, Result, colon, close quotes, right parenthesis, semicolon, forward slash, forward slash, label for result. Line 30, indented twice: result, equals, new, J Label, left parenthesis, open quotes, question mark, question mark, question mark, close quotes, right parenthesis, semicolon, forward slash, forward slash, label to hold result. Line 31: Blank. Line 32, indented twice: forward slash, forward slash, add components to the window. Line 33, indented twice: contents, dot, add, left parenthesis, operand Label, right parenthesis, semicolon. Line 34, indented twice: contents, dot, add, left parenthesis, operand, right parenthesis, semicolon. Line 35, indented twice: contents, dot, add, left parenthesis, square, right parenthesis, semicolon. Line 36, indented twice: contents, dot, add, left parenthesis, cube, right parenthesis, semicolon. Line 37, indented twice: contents, dot, add, left parenthesis, result Label, right parenthesis, semicolon. Line 38, indented twice: contents, dot, add, left parenthesis, result, right parenthesis, semicolon. Line 39: Blank. Line 40, indented twice: forward slash, forward slash, instantiate our event handler. Line 41, indented twice: Button Handler, b h, equals, new, Button Handler, left parenthesis, right parenthesis, semicolon. Line 42: Blank. Line 43, indented twice: Forward slash, forward slash, add event handler as listener for both buttons. Line 44, indented twice: square, dot, add Action Listener, left parenthesis, b h, right parenthesis, semicolon. Line 45, indented twice: cube, dot, add Action Listener, left parenthesis, b h, right parenthesis, semicolon. Line 46: Blank. Line 47, indented twice: set Size, left parenthesis, 175, comma, 150, right parenthesis, semicolon. Line 48, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 49, indented once: Right brace. Line 50: Blank. Line 51, indented once. forward slash, forward slash, private inner class event handler. Line 52, indented once. private, class, Button Handler, implements, Action Listener. Line 53, indented once: left brace. Line 54, indented twice: forward slash, forward slash, implement action Performed method. Line 55, indented twice: public, void, action Performed, left parenthesis, Action Event, a e, right parenthesis. Line 56, indented twice: Left brace. Line 57, indented 3 times: try. Line 58, indented 3 times: Left brace. Line 59, indented 4 times: double, o p, equals, Double, dot, parse Double, left parenthesis, operand, dot, get Text, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 60: Blank. Line 61, indented 4 times: forward slash, forward slash, identify which button was pressed. Line 62, indented 4 times: if, left parenthesis, a e, dot, get Source, left parenthesis, right parenthesis, equals, equals, square, right parenthesis. Line 63, indented 5 times: result, dot, set Text, left parenthesis, Double, dot, value Of, left parenthesis, o p, asterisk, o p, right parenthesis, dot, to String, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 64, indented 4 times: else, if, left parenthesis, a e, dot, get Source, left parenthesis, right parenthesis, equals, equals, cube, right parenthesis. Line 65, indented 5 times: result, dot, set Text, left parenthesis, Double, dot, value Of, left parenthesis, o p, asterisk, o p, asterisk, o p, right parenthesis, dot, to String, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 66, indented 3 times: Right brace. Line 67, indented 3 times: catch, left parenthesis, Number Format Exception, e, right parenthesis. Line 68, indented 3 times: Left brace. Line 69, indented 4 times: operand Label, dot, set Text, left parenthesis, open quotes, Enter a number, close quotes, right parenthesis, semicolon. Line 70, indented 4 times: operand, dot, set Text, left parenthesis, open quotes, close quotes, right parenthesis, semicolon. Line 71, indented 4 times: result, dot, set Text, left parenthesis, open quotes, question mark, question mark, question mark, question mark, close quotes, right parenthesis, semicolon. Line 72, indented 3 times: Right brace. Line

73, indented twice: Right brace. Line 74, indented once: Right brace. Line 75: Blank. Line 76, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 77, indented once: Left brace. Line 78, indented twice: Simple Math, s m, equals, new, Simple Math, left parenthesis, right parenthesis, semicolon. Line 79, indented once: s m, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 80, indented once: Right brace. Line 81: Right brace.

Back to Example

Program code. In the code, the words in the variable names are merged. Line 1: public, void, action Performed, left parenthesis, Action Event, event, right parenthesis.

Back to Table

Code for a program that does simple math using J Button. Program code. In the code, the words in the variable names are merged. Line 79, indented twice: s m, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 80, indented once: Right brace. Line 81: Right brace.

Back to Example

A graphical user interface in which color can be selected using radio buttons and checkboxes. The first section of the graphical user interface has the heading, Using Radio Buttons. Only one selection is possible at a time. Three columns of radio buttons are present for color selection with three radio buttons in each column. The columns are labeled red, green, and blue. The resulting color combination in each row of radio buttons is listed in the adjacent column that is labeled Resulting Color. The second section of the graphical user interface has the heading, Using Checkboxes. Zero to three selections are possible at a time. Three columns of checkboxes are present for color selection with eight checkboxes in each column. The columns are labeled red, green, and blue. The resulting color combination in each row of checkboxes is listed in the adjacent column that is labeled Resulting Color.

Back to Table

A table detailing useful constructors of the J Radio Button, Button Group, and J Check Box classes. Constructors of the J Radio Button, Button Group, and J Check Box Classes. Constructors. The table has 5 rows and 2 columns. It has the following column headings. Class. Constructor. The row details of the table are the following. Row 1: Class, J Radio Button; Constructor, J Radio Button, left parenthesis, String, button Label, right parenthesis, constructs a radio button labeled button Label. By default, the radio button is initially deselected. Row 2: Class, J Radio Button; Constructor, J Radio Button, left parenthesis, String, button Label, comma, boolean, selected, right parenthesis, constructs a radio button labeled button Label. If selected is true, the button is initially selected; if selected is false, the button is deselected. Row 3: Class, Button Group; Constructor, Button Group, left parenthesis, right parenthesis, constructs a button group. Adding buttons to this group makes the buttons mutually exclusive. Row 4: Class, J Check Box; Constructor, J Check Box, J Check Box, left parenthesis, String, check Box Label, right parenthesis, constructs a checkbox labeled check Box Label. By default, the checkbox is initially deselected. Row 5: Class, J Check Box; Constructor, J Check Box, left parenthesis, String, check Box Label, comma, boolean, selected, right parenthesis, constructs a checkbox labeled check Box Label. If selected is true, the checkbox is initially selected; if selected is false, the checkbox is initially deselected.

Back to Table

The Item Listener method A P I. public, void, item State Changed, left parenthesis, Item Event, event, right parenthesis. An event handler that implements the Item Listener interface writes code in this method to respond to the Item Event fired by any registered components.

Back to Table

Code for a program in which colors can be selected using J Radio Buttons. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Select a Color using J Radio Buttons. Line 2: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x dot swing dot asterisk, semicolon. Line 6: import, java dot a w t dot asterisk, semicolon. Line 7: import, java dot a w t dot event dot asterisk, semicolon. Line 8: Blank. Line 9: public, class, Changing Colors, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, Container, contents, semicolon. Line 12, indented once: private, J Radio Button, red, comma, green, comma, blue, semicolon. Line 13, indented once: private, Button Group, color Group, semicolon. Line 14, indented once: private, J Label, label, semicolon. Line 15, indented once: private, Color, selected Color, equals, Color dot RED, semicolon. Line 16: Blank. Line 17, indented once: public, Changing Colors, left parenthesis, right parenthesis. Line 18, indented once: Left brace. Line 19, indented twice: super, left parenthesis, open quotes, Selecting a color, close quotes, right parenthesis, semicolon. Line 20, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 21, indented twice: contents, dot, set Layout, left parenthesis, new, Flow Layout, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 22: Blank. Line 23, indented twice: red, equals, new, J Radio Button, left parenthesis, open quotes, red, close quotes, comma, true, right parenthesis, semicolon. Line 24, indented twice: green, equals, new, J Radio Button, left parenthesis, open quotes, green, close quotes, right parenthesis, semicolon. Line 25, indented twice: blue, equals, new, J Radio Button, left parenthesis, open quotes, blue, close quotes, right parenthesis, semicolon. Line 26: Blank. Line 27, indented twice: label, equals, new, J Label, left parenthesis, open quotes, Watch my background, close quotes, right parenthesis, semicolon. Line 28, indented twice: label, dot, set Foreground, left parenthesis, Color, dot, GRAY, right parenthesis, semicolon. Line 29, indented twice: label, dot, set Opaque, left parenthesis, true, right parenthesis, semicolon. Line 30, indented twice: label, dot, set Background, left parenthesis, selected Color, right parenthesis, semicolon. Line 31: Blank. Line 32, indented twice: contents, dot, add, left parenthesis, red, right parenthesis, semicolon. Line 33, indented twice: contents, dot, add, left parenthesis, green, right parenthesis, semicolon. Line 34, indented twice: contents, dot, add, left parenthesis, blue, right parenthesis, semicolon. Line 35, indented twice: contents, dot, add, left parenthesis, label, right parenthesis, semicolon. Line 36: Blank. Line 37, indented twice: Forward slash, forward slash, create button group. Line 38, indented twice: color Group, equals, new, Button Group, left parenthesis, right parenthesis, semicolon. Line 39, indented twice: color Group, dot, add, left parenthesis, red, right parenthesis, semicolon. Line 40, indented twice: color Group, dot, add, left parenthesis, green, right parenthesis, semicolon. Line 41, indented twice: color Group, dot, add, left parenthesis, blue, right parenthesis, semicolon. Line 42: Blank. Line 43, indented twice: forward slash, forward slash, create Radio Button Handler event handler. Line 44, indented twice: forward slash, forward slash, and register it on the radio buttons. Line 45, indented twice: Radio Button Handler, r b h, equals, new, Radio Button Handler, left parenthesis, right parenthesis, semicolon. Line 46, indented twice: red, dot, add Item Listener, left parenthesis, r b h, right parenthesis, semicolon. Line 47, indented twice: green, dot, add Item Listener, left parenthesis, r b h, right parenthesis, semicolon. Line 48, indented twice: blue, dot, add Item Listener, left parenthesis, r b h, right parenthesis, semicolon. Line 49: Blank. Line 50, indented twice: set Size, left parenthesis, 225, comma, 200, right parenthesis, semicolon. Line 51, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 52, indented once: Right brace. Line 53: Blank. Line 54, indented once: private, class, Radio Button Handler, implements, Item Listener. Line 55, indented once: Left brace. Line 56, indented twice: public, void, item State Changed, left parenthesis, Item Event, i e, right parenthesis. Line 57, indented twice: Left brace. Line 58, indented 3 times: if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, red, right parenthesis. Line 59, indented 4 times: selected Color, equals, Color, dot, RED, semicolon. Line 60, indented 3 times: else, if, left parenthesis, i e, dot, get

Source, left parenthesis, right parenthesis, equals, equals, green, right parenthesis. Line 61, indented 4 times: selected Color, equals, Color, dot, GREEN, semicolon. Line 62, indented 3 times: else, if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, blue, right parenthesis. Line 63, indented 4 times: selected Color, equals, Color, dot, BLUE, semicolon. Line 64: Blank. Line 65, indented 3 times: label, dot, set Background, left parenthesis, selected Color, right parenthesis, semicolon. Line 66, indented twice: Right brace. Line 67, indented once: Right brace. Line 68: Blank. Line 69, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 70, indented once: Left brace. Line 71, indented twice: Changing Colors, c c, equals, new, Changing Colors, left parenthesis, right parenthesis, semicolon. Line 72, indented twice: c c, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 73, indented once: Right brace. Line 74: Right brace.

Code for a program that uses J Check Boxes. Program code. In the code, the words in the variable names are merged. Line 1, forward slash, asterisk, Using J Check Boxes. Line 2 Anderson, comma, Franceschi. Line 3, asterisk, forward slash. Line 4: Blank. Line 5: import, java x dot swing dot asterisk, semicolon. Line 6: import, java dot a w t dot asterisk, semicolon. Line 7: import, java dot a w t dot event dot asterisk, semicolon. Line 8: Blank. Line 9: public, class, Mixing Colors, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, Container, contents, semicolon. Line 12, indented once: private, J Check Box, red, comma, green, comma, blue, semicolon. Line 13, indented once: private, i n t, red Value, comma, green Value, comma, blue Value, semicolon. Line 14, indented once: private, J Label, label, semicolon. Line 15: Blank. Line 16, indented once: public, Mixing Colors, left parenthesis, right parenthesis. Line 17, indented once: Left brace. Line 18, indented once: super, left parenthesis, open quotes, Selecting a color, close quotes, right parenthesis, semicolon. Line 19, indented once: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 20, indented once: contents, dot, set Layout, left parenthesis, new, Flow Layout, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 21: Blank. Line 22, indented once: red, equals, new, J Check Box, left parenthesis, open quotes, red, close quotes, semicolon, semicolon. Line 23, indented once: green, equals, new, J Check Box, left parenthesis, open quotes, green, close quotes, right parenthesis, semicolon. Line 24, indented once: blue, equals, new, J Check Box, left parenthesis, open quotes, blue, close quotes, right parenthesis, semicolon. Line 25: Blank. Line 26, indented once: label, equals, new, J Label, left parenthesis, open quotes, Watch my background, close quotes, right parenthesis, semicolon.

Line 27, indented once: label, dot, set Opaque, left parenthesis, true, right parenthesis, semicolon. Line 28, indented once: label, dot, set Foreground, left parenthesis, Color, dot, GRAY, right parenthesis, semicolon. Line 29, indented once: label, dot, set Background, left parenthesis, new, Color, left parenthesis, 0, comma, 0, comma, 0, right parenthesis, right parenthesis, semicolon. Line 30: Blank. Line 31, indented once: contents, dot, add, left parenthesis, red, right parenthesis, semicolon. Line 32, indented once: contents, dot, add, left parenthesis, green, right parenthesis, semicolon. Line 33, indented once: contents, dot, add, left parenthesis, blue, right parenthesis, semicolon. Line 34, indented once: contents, dot, add, left parenthesis, label, right parenthesis, semicolon. Line 35: Blank. Line 36, indented once: forward slash, forward slash, create Check Box Handler event handler. Line 37, indented once: forward slash, forward slash, and register it on the checkboxes. Line 38, indented once: Check Box Handler, c b h, equals, new, Check Box Handler, left parenthesis, right parenthesis, semicolon. Line 39, indented once: red, dot, add Item Listener, left parenthesis, c b h, right parenthesis, semicolon. Line 40, indented once: green, dot, add Item Listener, left parenthesis, c b h, right parenthesis, semicolon. Line 41, indented once: blue, dot, add Item Listener, left parenthesis, c b h, right parenthesis, semicolon. Line 42: Blank. Line 43, indented once: set Size, left parenthesis, 225, comma, 200, right parenthesis, semicolon. Line 44, indented once: set

Visible, left parenthesis, true, right parenthesis, semicolon. Line 45, indented once: Right brace. Line 46: Blank. Line 47, indented once: private, class, Check Box Handler, implements, Item Listener. Line 48, indented once: Left brace. Line 49, indented twice: public, void, item State Changed, left parenthesis, Item Event, i e, right parenthesis. Line 50, indented twice: Left brace. Line 51, indented 3 times: if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, red, right parenthesis. Line 52, indented 3 times: Left brace. Line 53, indented 4 times: if, left parenthesis, i e, dot, get State Change, left parenthesis, right parenthesis, equals, equals, Item Event, dot, SELECTED, right parenthesis. Line 54, indented 5 times: red Value, equals, 255, semicolon. Line 55, indented 4 times: else. Line 56, indented 5 times: red Value, equals, 0, semicolon. Line 57, indented 3 times: Right brace. Line 58, indented 3 times: else, if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, green, right parenthesis. Line 59, indented 3 times: Left brace. Line 60, indented 4 times: if, left parenthesis, i e, dot, get State Change, left parenthesis, right parenthesis, equals, equals, Item Event, dot, SELECTED, right parenthesis. Line 61, indented 5 times: green Value, equals, 255, semicolon. Line 62, indented 4 times: else. Line 63, indented 5 times: green Value, equals, 0, semicolon. Line 64, indented 3 times: Right brace. Line 65, indented 3 times: else, if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, blue, right parenthesis. Line 66, indented 3 times: Left brace. Line 67, indented 4 times: if, left parenthesis, i e, dot, get State Change, left parenthesis, right parenthesis, equals, equals, Item Event, dot, SELECTED, right parenthesis. Line 68, indented 5 times: blue Value, equals, 255, semicolon. Line 69, indented 4 times: else. Line 70, indented 5 times: blue Value, equals, 0, semicolon. Line 71, indented 3 times: Right brace. Line 72: Blank. Line 73, indented 3 times: label, dot, set Background, left parenthesis. Line 74, indented a few times: new, Color, left parenthesis, red Value, comma, green Value, comma, blue Value, right parenthesis, right parenthesis, semicolon. Line 75, indented twice: Right brace. Line 76, indented once: Right brace. Line 77: Blank. Line 78: indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 79, indented once. Left brace. Line 80, indented twice: Mixing Colors, m c, equals, new, Mixing Colors, left parenthesis, right parenthesis, semicolon. Line 81, indented twice: m c, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 82, indented once: Right brace. Line 83: Right brace.

Back to Example

A table detailing a useful method of the Item Event class. The return value of the method is i n t. The method name and argument list is the following. get State Change, left parenthesis, right parenthesis, returns the state of the checkbox. If the checkbox is selected, the value SELECTED is returned; if the checkbox is deselected, the value DESELECTED is returned, where SELECTED and DESELECTED are static i n t constants of the Item Event class.

The location of Student Code in the program J Button Practice dot java. Program code. In the code, the words in the variable names are merged. Line 1, indented once: dot, dot, dot. Line 2, indented once: open, equals, new, J Button, left parenthesis, open quotes, OPEN, close quotes, right parenthesis, semicolon. Line 3, indented once: contents, dot, add, left parenthesis, open, right parenthesis, semicolon. Line 4, indented once: close, equals, new, J Button, left parenthesis, open quotes, CLOSE, close quotes, right parenthesis, semicolon. Line 5, indented once: contents, dot, add, left parenthesis, close, right parenthesis, semicolon. Line 6, indented once: Forward slash, forward slash, a few asterisks, 1. Student code starts here. Line 7, indented once: forward slash, forward slash, declare and instantiate the button handler. Line 8, indented once: forward slash, forward slash, and register it on the buttons. Line 9, indented once: forward slash, forward slash, end of task 1. Line 10, indented once: set Size, left parenthesis, 500, comma, 375, right parenthesis, semicolon. Line 11, indented once: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 12: Right brace. Line 13: forward slash, forward slash, a few asterisks, 2. Student code restarts here. Line 14: forward slash, forward slash, Code a private class to implement the correct Listener. Line 15: forward slash, forward slash, and its required method. Line 16: forward slash, forward slash, To open the switch, call the open method with the statement. Line 17: forward slash, forward slash, open, left parenthesis, right parenthesis, semicolon. Line 18: forward slash, forward slash, To close the switch, call the close method with the statement. Line 19: forward slash, forward slash, close, left parenthesis, right parenthesis, semicolon. Line 20: forward slash, forward slash, The last statement of the method should be. Line 21: forward slash, forward slash, animate, left parenthesis, right parenthesis, semicolon. Line 22: forward slash, forward slash, end of task 2.

Back to Example

A table detailing useful constructors and methods of the J Combo Box class. Constructor. Class: J Combo Box. Constructor. J Combo Box, left parenthesis, Object, left square brace, right square brace, array Name, right parenthesis, constructs a new J Combo Box component initially filled with the objects in array Name. Often, the objects are Strings. Methods. The table has 3 rows and 2 columns. The column headings in the table are the following. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set Selected Index, left parenthesis, i n t, index, right parenthesis, sets the item at index as selected. The index of the first item in the list is 0. Row 2: Return value, i n t; Method name and argument list, get Selected Index, left parenthesis, right parenthesis, returns the index of the selected item. The index of the first item in the list is 0. Row 3: Return value, void; Method name and argument list, set Maximum Row Count, left parenthesis, i n t, size, right parenthesis, sets the number of rows that will be visible at one time to size.

Back to Table

Code for a program that uses J Combo Box to display food samplings. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Using J Combo Box to show a sampling of international foods. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x, dot, swing, dot, asterisk, semicolon. Line 6: import, java, dot, a w t, dot, asterisk, semicolon. Line 7: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 8: Blank. Line 9: public, class, Food Samplings, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, Container, contents, semicolon. Line 12, indented once: private, J Combo Box, left angle bracket, String, right angle bracket, countries, semicolon. Line 13, indented once: private, J Label, food Image, semicolon. Line 14: Blank. Line 15, indented once: private, String, left square brace, right square brace, country List, equals, Line 16, indented a few times: Left brace, open quotes, France, close quotes, comma, open quotes, Greece, close quotes, comma, open quotes, Italy, close quotes, comma, open quotes, Japan, close quotes, comma, open quotes, U S A, close quotes, right brace, semicolon. Line 17, indented once: private, Image Icon, left square brace, right square brace, foods, equals. Line 18, indented a few times: Left brace, new Image Icon, open quotes, cheese, dot, j p g, close quotes, right parenthesis, comma. Line 19, indented a few times: new, Image Icon, left parenthesis, open quotes, feta Salad, dot, j p g, close quotes, right parenthesis, comma. Line 20, indented a few times: new, Image Icon, left parenthesis, open quotes, pizza, dot, j p g, close quotes, right parenthesis, comm. Line 21, indented a few times: new, Image Icon, left parenthesis, open quotes, sushi, dot, j p g, close quotes, right parenthesis, comma. Line 22, indented once: new, Image Icon, left parenthesis, open quotes, hamburger, dot, j p g, close quotes, right parenthesis, right brace, semicolon. Line 23: Blank. Line 24, indented once: public, Food Samplings, left parenthesis, right parenthesis. Line 25, indented once: Left brace. Line 26, indented twice: super, left parenthesis, open quotes, Food samplings of various countries, close quotes, right parenthesis, semicolon. Line 27, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 28, indented twice: contents, dot, set Layout, left parenthesis, new, Flow Layout, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 29: Blank. Line 30, indented twice: forward slash, forward slash, instantiate the components. Line 31, indented twice: countries, equals, new, J Combo Box, left angle bracket, String, right angle bracket, left parenthesis, country List, right parenthesis, semicolon. Line 32, indented twice: countries, dot, set Maximum Row Count, left parenthesis, 4, right parenthesis, semicolon. Line 33, indented twice: countries, dot, set Selected Index, left parenthesis, 2, right parenthesis, semicolon. Line 34, indented twice: food Image, equals, new, J Label, left parenthesis, foods, left square brace, 2, right square brace, right parenthesis, semicolon. Line 35: Blank. Line 36, indented twice: forward slash, forward slash, add components to the content pane. Line 37, indented twice: contents, dot, add, left parenthesis, countries, right parenthesis, semicolon. Line 38, indented twice: contents, dot, add, left parenthesis, food Image, right parenthesis, semicolon. Line 39: Blank. Line 40, indented twice: forward slash, forward slash, set up event handler. Line 41, indented twice: Item Listener Handler, i l h, equals, new, Item Listener Handler, left parenthesis, right parenthesis, semicolon. Line 42, indented twice: countries, dot, add Item Listener, left parenthesis, i l h, right parenthesis, semicolon. Line 43: Blank. Line 44, indented twice: set Size, left parenthesis, 350, comma, 150, right parenthesis, semicolon. Line 45, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 46, indented once: right brace. Line 47: Blank. Line 48, indented once: private, class, Item

Listener Handler, implements, Item Listener. Line 49, indented once: left brace. Line 50, indented twice: public, void, item State Changed, left parenthesis, Item Event, i e, right parenthesis, Line 51, indented twice: Left brace. Line 52, indented 3 times: i n t, index, equals, countries, dot, get Selected Index, left parenthesis, right parenthesis, semicolon. Line 53, indented 3 times: food Image, dot, set Icon, left parenthesis, foods, left square brace, index, right square brace, right parenthesis, semicolon. Line 54, indented twice: Right brace. Line 55, indented once: Right brace. Line 56: Blank. Line 57, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 58, indented once: left brace. Line 59, indented twice: Food Samplings, f s, equals, new, Food Samplings, left parenthesis, right parenthesis, semicolon. Line 60, indented twice: f s, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 61, indented once: Right brace. Line 62: Right brace.

Back to Example

A table detailing useful methods of the Mouse Event class. The table has 2 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, i n t; Method name and argument list, get X, left parenthesis, right parenthesis, returns the x value of the (x, comma, y) coordinate of the mouse activity. Row 2: Return value, i n t; Method name and argument list, get Y, left parenthesis, right parenthesis, returns the y value of the (x, comma, y) coordinate of the mouse activity.

Back to Table

A table detailing methods of the Mouse Listener interface. Mouse Listener Interface Method A P Is. The row details in the table are the following. Row 1: public, void, mouse Pressed, left parenthesis, Mouse Event, e, right parenthesis, called when the mouse button is pressed. Row 2: public, void, mouse Released, left parenthesis, Mouse Event, e, right parenthesis, called when the mouse button is released after being pressed. Row 3: public, void, mouse Clicked, left parenthesis, Mouse Event, e, right parenthesis, called when the mouse button is pressed and released. Row 4: public, void, mouse Entered, left parenthesis, Mouse Event, e, right parenthesis, called when the mouse enters the registered component. Row 5: public, void, mouse Exited, left parenthesis, Mouse Event, e, right parenthesis, called when the mouse exits the registered component.

Back to Table

Code for the Sub Hunt class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Sub Hunt class. Line 2 *

Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java, dot, a w t, dot, Graphics, semicolon. Line 6: import, java, dot, a w t, dot, Color, semicolon. Line 7: import, java, dot, util, dot, Random, semicolon. Line 8: Blank. Line 9: public, class, Sub Hunt. Line 10: Left brace. Line 99, indented 3 times: g, dot, draw Line, left parenthesis, x C t r, plus, SIDE, forward slash, 4, comma, y C t r, minus, SIDE, forward slash, 9, comma. Line 100, indented a few times: x C t r, plus, SIDE, forward slash, 2, comma, y C t r, minus, SIDE, forward slash, 9, right parenthesis, semicolon. Line 101: Blank. Line 102, indented 3 times: forward slash, forward slash, draw red depth charge. Line 103, indented 3 times: g, dot, set Color, left parenthesis, Color, dot, RED, right parenthesis, semicolon. Line 104, indented a few times: g, dot, fill Oval, left parenthesis, x, minus, SIDE, forward slash, 4, comma, y, minus, SIDE, forward slash, 4, comma, SIDE, forward slash, 2, comma, SIDE, forward slash, 2, right parenthesis, semicolon. Line 105, indented twice: Right brace. Line 106, indented twice: else, if, left parenthesis, status, dot, equals, left parenthesis, open quotes, In the water, close quotes, right parenthesis, right parenthesis, forward slash, forward slash, draw blue circle. Line 107, indented twice: Left brace. Line 108, indented 3 times: g, dot, set Color, left parenthesis, Color, dot, BLUE, right parenthesis, semicolon. Line 109, indented 3 times: g, dot, fill Oval, left parenthesis, x, minus, SIDE, forward slash, 2, comma, y, minus, SIDE, forward slash, 2, comma, SIDE, comma, SIDE, right parenthesis, semicolon. Line 110, indented twice: Right brace. Line 111, indented twice: forward slash, forward slash, else, Close, dot, dot, dot, comma, do not draw. Line 112, indented once: Right brace. Line 113: Right brace.

Back to Example

Code for the Sub Hunt View Controller class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Sub Hunt View Controller class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x, dot, swing, dot, asterisk, semicolon. Line 6: import, java, dot, a w t, dot, asterisk, semicolon. Line 7: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 8: Blank. Line 9: public, class, Sub Hunt View Controller, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, i n t, x, semicolon, forward slash, current x mouse position. Line 12, indented once: private, i n t, y, semicolon, forward slash, forward slash, current y mouse position. Line 13, indented once: private, Sub Hunt, sub, semicolon, forward slash, forward slash, submarine. Line 14, indented once: private, boolean, game Started, equals, false, semicolon. Line 15, indented once: private, Insets, insets, semicolon. Line 16, indented once: private, Mouse Handler, m h, semicolon, forward slash, forward slash, mouse event handler. Line

17: Blank. Line 18, indented once: public, Sub Hunt View Controller, left parenthesis, Sub Hunt, new Sub, right parenthesis. Line 19, indented once: Left brace. Line 20, indented twice: super, left parenthesis, open quotes, Play, exclamation mark, close quotes, right parenthesis, semicolon. Line 21: Blank. Line 22, indented twice: sub, equals, new Sub, semicolon. Line 23, indented twice: forward slash, forward slash, instantiate event handler and register listener on window. Line 24, indented twice: m h, equals, new, Mouse Handler, left parenthesis, right parenthesis, semicolon. Line 25, indented twice: add Mouse Listener, left parenthesis, m h, right parenthesis, semicolon. Line 26: Blank. Line 27, indented twice: forward slash, forward slash, size window to include insets. Line 28, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 29, indented twice: insets, equals, get Insets, left parenthesis, right parenthesis, semicolon. Line 30, indented twice: set Size, left parenthesis, sub, dot, get Game Size, left parenthesis, right parenthesis, plus, insets, dot, left, plus, insets, dot, right, comma. Line 31, indented a few times: sub, dot, get Game Size, left parenthesis, right parenthesis, plus, insets, dot, top, plus, insets, dot, bottom, right parenthesis, semicolon. Line 32, indented once: Right brace. Line 33: Blank. Line 34, indented once: private, class, Mouse Handler, extends, Mouse Adapter. Line 35, indented once: Left brace. Line 36, indented twice: public, void, mouse Clicked, left parenthesis, Mouse Event, m e, right parenthesis. Line 37, indented twice: Left brace. Line 38, indented 3 times: x, equals, m e, dot, get X, left parenthesis, right parenthesis, minus, insets, dot, left, semicolon. Line 39, indented 3 times: y, equals, m e, dot, get Y, left parenthesis, right parenthesis, minus, insets, dot, top, semicolon. Line 40, indented 3 times: sub, dot, play, left parenthesis, x, comma, y, right parenthesis, semicolon. Line 41, indented 3 times: set Title, left parenthesis, sub, dot, get Status, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 42, indented 3 times: repaint, left parenthesis, right parenthesis, semicolon. Line 43, indented twice: Right brace. Line 44, indented once: Right brace. Line 45: Blank. Line 46, indented once: public, void, paint, left parenthesis, Graphics, g, right parenthesis. Line 47, indented once: Left brace. Line 48, indented twice: if, left parenthesis, exclamation mark, game Started, right parenthesis. Line 49, indented twice: Left brace. Line 50, indented 3 times: super, dot, paint, left parenthesis, g, right parenthesis, semicolon. Line 51, indented 3 times: game Started, equals, true, semicolon. Line 52, indented twice: Right brace. Line 53, indented twice: g, dot, translate, left parenthesis, insets, dot, left, comma, insets, dot, top, right parenthesis, semicolon. Line 54, indented twice: sub, dot, draw, left parenthesis, g, comma, x, comma, y, right parenthesis, semicolon. Line 55, indented twice: if, left parenthesis, sub, dot, is Hit, left parenthesis, right parenthesis, right parenthesis. Line 56, indented 3 times: remove Mouse Listener, left parenthesis, m h, right parenthesis, semicolon. Line 57, indented twice: Right brace. Line 58: Right brace.

Back to Example

A table detailing the get Insets method inherited from the Container class. Method: Insets, get Insets, left parenthesis, right parenthesis. Description: Returns an object representing the insets of this Container.

Back to Table

A table detailing the instance variables of the Insets class. The table has 4 rows and 2 columns. It has the following column headings. Instance Variables. Description. The row details in the table are the following. Row 1: Instance Variable, public, i n t top; Description, The size of the top border. Row 2: Instance Variable, public, i n t, left; Description, The size of the left border. Row 3: Instance Variable, public, i n t, bottom; Description, The size of the bottom border. Row 4: Instance Variable, public, i n t, right; Description, The size of the right border.

Back to Table

A table detailing the repaint method A P I in the component class. The return value is void. The method name and argument list is repaint, left parenthesis, right parenthesis. This method automatically forces a call to the paint method.

Back to Table

A table detailing the translate method of the Graphics class. The method is void, translate, left parenthesis, i n t, x, comma, i n t, y, right parenthesis. This method translates the origin of the graphics context to the point x, comma, y in the current coordinate system.

Back to Table

Code for the Play Sub Hunt class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Play Sub Hunt class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x, dot, swing, dot, J Frame, semicolon. Line 6: Blank. Line 7: public, class, Play Sub Hunt. Line 8: Left brace. Line 9, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 10, indented once: Left brace. Line 11, indented twice: Sub Hunt, sub, equals, new, Sub Hunt, left parenthesis, Sub Hunt, dot, DEFAULT underscore GAME underscore SIZE, right parenthesis, semicolon. Line 12, indented once: Sub Hunt View Controller, sub G u i, equals, new, Sub Hunt View Controller, left parenthesis, sub, right parenthesis, semicolon. Line 13, indented once: sub G u i, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 14, indented once: Right brace. Line 15: Right brace.

Back to Example

A table detailing the Mouse Motion Listener Interface method A P Is. Row 1: public, void, mouse Moved, left parenthesis, Moue Event, e, right parenthesis, called when the mouse is moved onto a component. Row 2: public, void, mouse Dragged, left parenthesis, Mouse Event, e, right parenthesis, called when the mouse button is pressed on a component and the mouse is dragged.

Back to Table

Code for the Treasure Hunt class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Treasure Hunt class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java, dot, a w t, dot, asterisk, semicolon. Line 6: import, java, dot, util, dot, Random, semicolon. Line 7: Blank. Line 8: public, class, Treasure Hunt. Line 9: Left brace. Line 10, indented once: public, static, i n t, DEFAULT underscore GAME underscore SIZE, equals, 300, semicolon, forward slash, forward slash, side of window. Line 11, indented once: public, static, i n t, SIDE, equals, 40, semicolon, forward slash, forward slash, side of treasure. Line 12: Blank. Line 13, indented once: private, i n t, game Size, semicolon. Line 14, indented once: private, i n t, x C t r, semicolon, forward slash, forward slash, x coordinate of center of treasure. Line 15, indented once: private, i n t, y C t r, semicolon, forward slash, forward slash, y coordinate of center of treasure. Line 16, indented once: private, String, status, equals, open quotes, close quotes, semicolon, forward slash, forward slash, message. Line 17, indented once: private, boolean, game Over, equals, false, semicolon. Line 18: Blank. Line 19, indented once: Forward slash, asterisk, asterisk, Constructor. Line 20, indented once: Asterisk, forward slash. Line 21, indented once: public, Treasure Hunt, left parenthesis, i n t, new Game Size, right parenthesis. Line 22, indented once: Left brace. Line 23, indented twice: if, left parenthesis, new Game Size, greater than, SIDE, right parenthesis. Line 24, indented 3 times: game Size, equals, new Game Size, semicolon. Line 25, indented twice: else. Line 26, indented 3 times: game Size, equals, DEFAULT underscore GAME underscore SIZE, semicolon. Line 27, indented twice: forward slash, forward slash, generate treasure center. Line 28, indented twice: Random, random, equals, new, Random, left parenthesis, right parenthesis, semicolon. Line 29, indented twice: x C t r, equals, SIDE, forward slash, 2, plus, random, dot, next I n t, left parenthesis, game Size, minus, SIDE, right parenthesis, semicolon. Line 30, indented twice: y C t r, equals, SIDE, forward slash, 2, plus, random, dot, next I n t, left parenthesis, game Size, minus, SIDE, right parenthesis, semicolon. Line 31, indented once: Right brace. Line 32: Blank. Line 33, indented once: forward slash, asterisk, asterisk, get Game Size. Line 34, indented once: asterisk, at, return, game Size. Line 35, indented once: asterisk, forward slash. Line 36, indented once:

public, i n t, get Game Size, left parenthesis, right parenthesis. Line 37, indented once: Left brace. Line 38, indented twice: return, game Size, semicolon. Line 39, indented once: Right brace. Line 40: Blank. Line 41, indented once: forward slash, asterisk, asterisk, is Game Over. Line 42, indented once: asterisk, @, return, game Over. Line 43, indented once: Asterisk, forward slash. Line 44, indented once: public, boolean, is Game Over, left parenthesis, right parenthesis. Line 45, indented once: Left brace. Line 46, indented twice: return, game Over, semicolon. Line 47, indented once: Right brace. Line 48: Blank. Line 49, indented once: forward slash, asterisk, asterisk, play. Line 50, indented once: asterisk, at, param, x, the x coordinate of the play. Line 51, indented once: asterisk, at, param, y, the y coordinate of the play. Line 52, indented once: asterisk, forward slash. Line 53, indented once: public, void, play, left parenthesis, i n t, x, comma, i n t, y, right parenthesis. Line 54, indented once: Left brace. Line 55, indented twice: forward slash, forward slash, is mouse within treasure? Line 56, indented twice: if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, SIDE, forward slash, 2. Line 57, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, SIDE, forward slash, 2, right parenthesis. Line 58, indented twice: Left brace. Line 59, indented 3 times: game Over, equals, true, semicolon. Line 60, indented 3 times: status, equals, open quotes, Found, close quotes, semicolon. Line 61, indented twice:

Right brace. Line 62, indented twice: forward slash, forward slash, is mouse within half-length of the treasure? Line 63, indented twice: else, if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, left parenthesis, 1.5, asterisk, SIDE, right parenthesis. Line 64, indented a few tiems: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, left parenthesis, 1.5, asterisk, SIDE, right parenthesis, right parenthesis. Line 65, indented 3 times: status, equals, open quotes, Hot, close quotes, semicolon. Line 66, indented twice: forward slash, forward slash, is mouse within 1 length of the treasure? Line 67, indented twice: else, if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, left parenthesis, 2, asterisk, SIDE, right parenthesis. Line 68, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, left parenthesis, 2, asterisk, SIDE, right parenthesis, right parenthesis. Line 69, indented 3 times: status, equals, open quotes, Warm, close quotes, semicolon. Line 70, indented twice: forward slash, forward slash, is mouse within 2 lengths of the treasure? Line 71, indented once: else, if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, left parenthesis, 3, asterisk, SIDE, right parenthesis. Line 72, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, left parenthesis, 3, asterisk, SIDE, right parenthesis, right parenthesis. Line 73, indented 3 times: status, equals, open quotes, Lukewarm, close quotes, semicolon. Line 74, indented twice: else, forward slash, forward slash, mouse is not near treasure. Line 75, indented 3 times: status, equals, open quotes, Cold, close quotes, semicolon. Line 76, indented once: Right brace. Line 77: Blank. Line 78, indented once: forward slash, asterisk, asterisk, draw. Line 79, indented once: asterisk, at, param, g, a Graphics object. Line 80, indented once: asterisk, at, param, x, the x coordinate of the play. Line 81, indented once: Asterisk, at, param, y, the y coordinate of the play. Line 82, indented once: Asterisk, forward slash. Line 83, indented once: public, void, draw, left parenthesis, Graphics, g, comma, i n t, x, comma, i n t, y, right parenthesis. Line 84, indented once: Left brace. Line 85, indented twice: g, dot, set Color, left parenthesis, Color, dot, BLUE, right parenthesis, semicolon. Line 86: Blank. Line 87, indented twice: if, left parenthesis, status, dot, equals, left parenthesis, open quotes, Found, close quotes, right parenthesis, right parenthesis, forward slash, forward slash, if found, comma, draw treasure. Line 88, indented twice: Left brace. Line 89, indented 3 times: g, dot, set Color, left parenthesis, Color, dot, RED, right parenthesis, semicolon. Line 90, indented 3 times: g, dot, fill Rect, left parenthesis, x C t r, minus, SIDE, forward slash, 2, comma, y C t r, minus, SIDE, forward slash, 2, comma, SIDE, comma, SIDE, right parenthesis, semicolon. Line 91, indented 3 times: g, dot, set Color, left parenthesis, Color, dot, GREEN, right parenthesis, semicolon. Line 92, indented 3 times: g, dot, draw String, left parenthesis, open quotes, dollar, dollar, dollar, close quotes, comma, x C t r, minus, SIDE, forward slash, 4, comma, y C t r, right parenthesis, semicolon. Line 93, indented twice: Right brace. Line 94, indented twice: else. Line 95, indented 3 times: g, dot, draw String, left parenthesis, status, comma, x, comma, y, right parenthesis, semicolon, forward slash, forward slash, display current status. Line 96, indented once: Right brace. Line 97: Right brace.

Line 16, indented once: Right brace. Line 17: Right brace.

Back to Example

A table detailing Grid Layout constructors. The table has two rows and two columns. It has the following column headings. Class. Constructor. The row details are the following. Row 1: Class, Grid Layout; Constructor, Grid Layout, left parenthesis, i n t, number Of Rows, comma, i n t, number Of Columns, right parenthesis, creates a grid layout with the number of rows and columns specified by the arguments. Row 2: Class, Grid Layout; Constructor, Grid Layout, left parenthesis, i n t, number Of Rows, comma, i n t, number Of Columns, comma, i n t, h Gap, comma, i n t, v Gap, right parenthesis, creates a grid layout with the specified number of rows and columns and with a horizontal gap of h Gap pixels between columns and a vertical gap of v Gap pixels between rows. Horizontal gaps are also placed at the left and right edges, and vertical gaps are placed at the top and bottom edges.

Back to Table

Code for the Chess Board class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Using Grid Layout to organize our window. Line 2 Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java x, dot, swing, dot, asterisk, semicolon. Line 6: import, java, dot, a w t, dot, asterisk, semicolon. Line 7: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 8: Blank. Line 9: public, class, Chess Board, extends, J Frame. Line 10: Left brace. Line 11, indented once: private, Container, contents, semicolon. Line 12, indented once: private, J Button, left square brace, right square brace, left square brace, right square brace, squares, semicolon. Line 13, indented once: private, String, left square brace, right square brace, letters, equals. Line 14, indented a few times: Left brace, open quotes, a, close quotes, comma, open quotes, b, close quotes, comma, open quotes, c, close quotes, comma, open quotes, d, close quotes, comma, open quotes, e, close quotes, comma, open quotes, f, close quotes, open quotes, g, close quotes, comma, open quotes, h, close quotes, right brace, semicolon. Line 15, indented once: private, i n t, left square brace, right square brace, digits, equals, left brace, 1, comma, 2, comma, 3, comma, 4, comma, 5, comma, 6, comma, 7, comma, 8, right brace, semicolon. Line 16: Blank. Line 17, indented once: public, Chess Board, left parenthesis, right parenthesis. Line 18, indented once: Left brace. Line 19, indented twice: super, left parenthesis, open quotes, Click a square to reveal its position, close quotes, right parenthesis, semicolon. Line 20, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 21: Blank. Line 22, indented twice: forward slash, forward slash, set layout to an 8-by-8 Grid. Line 23, indented twice: contents, dot, set Layout, left parenthesis, new, Grid Layout, left parenthesis, letters, dot, length, comma, digits, dot, length, right parenthesis, right parenthesis, semicolon. Line 24: Blank. Line 25, indented twice: squares, equals, new, J Button, left square brace, letters, dot, length, right square brace, left square brace, digits, dot, length, right square brace, semicolon. Line 16, indented once: Right brace. Line 17: Right brace.

Back to Example

A table detailing the Container add method for using a Border Layout. The table has the following details. Return value: void. Method name and argument list: add, left parenthesis, Component, c, comma, Object, border layout Area, right parenthesis, adds the component c to the container. The area defined by border layout Area can be specified using any of the following static String constants in the Border Layout class: NORTH, SOUTH, EAST, WEST, CENTER.

Back to Table

A table detailing Border Layout constructors. The table has 2 rows and 2 columns. It has the following column headings. Class. Constructor. The row details are the following. Row 1: Class, Border Layout; Constructor, Border Layout, left parenthesis, right parenthesis, creates a new border layout with no gaps between components. Row 2: Class, Border Layout; Constructor, Border Layout, left parenthesis, i n t, h Gap, comma, i n t, v Gap, right parenthesis, creates a border layout with a horizontal gap of h Gap pixels between components and a vertical gap of v Gap pixels between components. Unlike Grid Layout, horizontal gaps are not placed at the left and right edges, and vertical gaps are not placed at the top and bottom edges.

Back to Table

Code for the R G B Color Mixer class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, asterisk, R G B Color Mixer class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java, dot, a w t, dot, Color, semicolon. Line 6: Blank. Line 7: public, class, R G B Color Mixer. Line 8: Left brace. Line 9, indented once: public, static, i n t, POSITION underscore CHANGE, equals, 0, semicolon. Line 10, indented once: public, static, i n t, POSITION underscore RED, equals, 1, semicolon. Line 11, indented once: public, static, i n t, POSITION underscore GREEN, equals, 2, semicolon. Line 12, indented once: public, static, i n t, POSITION underscore BLUE, equals, 3, semicolon. Line 13: Blank. Line 14, indented once: private, i n t, delta, semicolon, forward slash, forward slash, color increment. Line 15, indented once: private, Color, color, semicolon, forward slash, mixed color. Line 16: Blank. Line 17, indented once: forward slash, asterisk, asterisk, Constructor. Line 18, indented once: Asterisk, at, param, new Delta, delta. Line 19, indented once: asterisk, forward slash. Line 20, indented once: public, R G B Color Mixer, left parenthesis, i n t, new Delta, right parenthesis. Line 21, indented once: Left brace. Line 22, indented twice: if, left parenthesis, new Delta, less than, minus 255, pipe, pipe, new Delta, greater than, 255, pipe, pipe, new Delta, equals, equals, 0, right parenthesis. Line 23, indented 3 times: delta, equals, 1, semicolon. Line 24, indented twice: else. Line 25, indented 3 times: delta, equals, new Delta, semicolon. Line 26, indented twice: if, left parenthesis, delta, greater than, 0, right parenthesis. Line 27, indented 3 times: color, equals, Color, dot, BLACK, semicolon. Line 28, indented twice: else. Line 29, indented 3 times: color, equals, Color, dot, WHITE, semicolon. Line 30, indented once: Right brace. Line 31: Blank. Line 32, indented once: forward slash, asterisk, asterisk, get Color method. Line 33, indented once: asterisk, at, return, color. Line 34, indented once: asterisk, forward slash. Line 35, indented once: public, Color, get Color, left parenthesis, right parenthesis. Line 36, indented once: Left brace. Line 37, indented twice: return, color, semicolon. Line 38, indented once: right brace. Line 39: Blank. Line 40, indented once: forward slash, asterisk, asterisk, invert Delta method. Line 41, indented once: asterisk, sets delta to its opposite. Line 42, indented once: asterisk, forward slash. Line 43, indented once: public, void, invert Delta, left parenthesis, right parenthesis. Line 44, indented once: Left brace. Line 45, indented twice: delta, equals, minus, delta, semicolon. Line 46, indented once: right brace. Line 47: Blank. Line 48, indented once: forward slash, asterisk, asterisk, add To Red method. Line 49, indented once: asterisk, add delta to red component of color. Line 50, indented once: Asterisk, forward slash. Line 51, indented once: public, void, add To Red, left parenthesis, right parenthesis. Line 52, indented once: Left brace. Line 53, indented twice: if, left parenthesis, color, dot, get Red, left parenthesis, right parenthesis, plus, delta, greater than, 255, right parenthesis. Line 54, indented 3 times: color, equals, new, Color, left parenthesis, 255, comma, color, dot, get Green, left parenthesis, right parenthesis, comma, color, dot, get Blue, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 55, indented twice: else, if, left parenthesis, color, dot, get Red, left parenthesis, right parenthesis, plus, delta, less than, 0, right parenthesis. Line 12: public class F X Shell Application extends Application. Line 13: left brace. Line 14, indented once: at symbol, Override. Line 15, indented once: 2 forward slashes, start is main entry point for the application. Line 16, indented once: 2 forward slashes. It receives a Stage object, hyphen, the main window for the. Line 17, indented once: 2 forward slashes. G U I application. Line 18, indented once: public void start, left parentheses, Stage stage, right parentheses, 2 forward slashes, throws exception. Line 19, indented once: left brace. Line 20, indented twice: try. Line 21, indented twice: left brace. Line 22, indented thrice: 2 forward slashes. Locate the F X M L resource. Line 23, indented thrice: U R L u r l. Line 24, indented 4 times: equals, get Class, left parentheses, right parentheses, dot, get Resource, left parentheses, double quotes, f x m l underscore shell dot f x m l, double quotes, right parentheses, semicolon. Line 25: blank. Line 26, indented thrice: 2 forward slashes. Load the F X M L resource, instantiate root node, semicolon. Line 27, indented thrice: 2 forward slashes. use appropriate layout class for root node, semicolon. Line 28, indented thrice: 2 forward slashes, here we use H Box. Line 29, indented thrice: H Box root, equals, F X M L Loader dot load, left parentheses, u r l, right parentheses, semicolon. Line 30: blank. Line 31, indented thrice: 2 forward slashes, create a scene associated with the root. Line 32, indented thrice: 2 forward slashes, and set its width and height. Line 33, indented thrice: Scene scene, equals, new Scene, left parentheses, root, comma, 300, comma, 275, right parentheses, semicolon. Line 34: blank. Line 35, indented thrice: 2 forward slashes, assign the scene to the stage object. Line 36, indented thrice: stage dot set Scene, left parentheses, scene, right parentheses, semicolon. Line 37: blank. Line 38, indented thrice: 2 forward slashes, set title of stage, left parentheses, optional, right parentheses. Line 39, indented thrice: stage dot set Title, left parentheses, double quotes, Java F X Shell, double quotes, right parentheses, semicolon. Line 40: blank. Line 41, indented thrice: 2 forward slashes, make the stage visible. Line 42, indented thrice: stage dot show, left parentheses, right parentheses, semicolon. Line 43, indented twice: right brace. Line 44, indented twice: 2 forward slashes, The F X M L Loader load method throws an exception if. Line 45, indented twice: 2 forward slashes, the F X M L file is invalid or the U R L was not found. Line 46, indented twice: catch, left parentheses, Exception e, right parentheses. Line 47, indented twice: left brace. Line 48, indented thrice: e dot print Stack Trace, left parentheses, right parentheses, semicolon. Line 49, indented twice: right brace. Line 50, indented once: right brace. Line 51: blank. Line 52, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 53, indented once: left brace. Line 54, indented twice: launch, left parentheses, a r g s, right parentheses, semicolon. Line 55, indented once: right brace. Line 56: right brace.

Back to Example

The methods are in the package java f x dot application. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: init, left parentheses, right parentheses, called by the Java F X runtime when the application is launched. Overriding this method is optional. Row 2. Return value: void. Method name and argument list: launch, left parentheses, String, dot, dot, dot, a r g s, right parentheses, static method that launches the application. Passes any command hyphen line arguments to the application. Row 3. Return value: Application dot Parameters. Method name and argument list: get Parameters, left parentheses, right parentheses, returns any command hyphen line arguments as an Application dot Parameters object. Row 4. Return value: void. Method name and argument list: start, left parentheses, Stage primary Stage, right parentheses, the main entry point for Java F X applications. The application places its scene onto the primary stage. This abstract method needs to be implemented. Row 5. Return value: void. Method name and argument list: stop, left parentheses, right parentheses, called when the application signals that it is ready to end. Overriding this method is optional.

Back to Table

The method is in the java dot lang package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: U R L. Method name and argument list: get Resource, left parentheses, String resource, right parentheses, returns a U R L object representing the location of the resource or null if the resource is not found.

Back to Table

The method is in the java f x dot f x m l package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: left angled bracket, uppercase t, right angled bracket, uppercase t. Method name and argument list: load, left parentheses, u r l location, right parentheses, static method that instantiates the nodes defined in the F X M L file specified by location and returns a reference to the root node.

Back to Table

The Scene method is in the java f x dot scene package. The constructor is as follows: Scene, left parentheses, Parent root, comma, double width, comma, double height, right parentheses, instantiates the Scene with a top level node of root and sets the width and height to the pixel values specified.

Back to Table

The methods are in the java f x dot stage package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: set Scene, left parentheses, Scene scene, right parentheses, specifies the scene to be hosted by the Stage. Row 2. Return value: void. Method name and argument list: set Title, left parentheses, String title, right parentheses, sets the text to appear in the window title bar. Row 3. Return value: void. Method name and argument list: show, left parentheses, right parentheses, makes the window visible. By default, windows are not visible.

Back to Table

Line 1: left angled bracket, question mark, x m l version, equals, double quotes, 1.0, double quotes, encoding, equals, double quotes, U T F hyphen 8, double quotes, question mark, right angled bracket. Line 2: blank. Line 3.

left angled bracket, exclamation mark, 2 hyphens, import classes, 2 hyphens, right angled bracket. Line 4: left angled bracket, question mark, import java f x dot scene dot layout dot H Box, question mark, right angled bracket. Line 5: blank. Line 6: left angled bracket, exclamation mark, 2 hyphens, use appropriate layout manager, 2 hyphens, right angled bracket. Line 7: left angled bracket, H Box x m l n s, colon, f x, equals, double quotes, h t t p, colon, 2 forward slashes, java f x ot com, forward slash, f x m l, double quotes, right angled bracket. Line 8, indented once: left angled bracket, exclamation mark, 2 hyphens, define G U I components here, 2 hyphens, right angled bracket. Line 9: left angled bracket, forward slash, H Box, right angled bracket.

Back to Example

The G U I controls are in the java f x dot scene dot control package. The table has 2 columns labeled Java F X Class and Purpose. The row entries are as follows. Row 1. Java F X Class: Label. Purpose: Displays an image or read hyphen only text. Labels are often used to identify the contents of Text Fields. Row 2. Java F X Class: Text Field. Purpose: A single hyphen line text box for accepting user input. Row 3. Java F X Class: Button. Purpose: Command button that the user clicks to signal that an operation should be performed. Row 4. Java F X Class: Radio Button. Purpose: Toggle button that the user clicks to select one option in a group. Row 5. Java F X Class: Check Box. Purpose: Toggle button that the user clicks to select or deselect 0, comma, 1, comma, or more options in a group. Row 6. Java F X Class: Combo Box. Purpose: List of options from which the user selects one item. Row 7. Java F X Class: Slider. Purpose: Displays a set of continuous values along a horizontal or vertical line. The user can select a value by moving the knob or thumb.

Back to Table

The classes are in the java f x dot scene dot layout package. The table has 2 columns labeled Layout Container and Lays out its children nodes. The row entries are as follows. Row 1. Layout Container: H Box. Lays out its children nodes: In a single horizontal row. Row 2. Layout Container: V Box. Lays out its children nodes: In a single vertical column. Row 3. Layout Container: Border Pane. Lays out its children nodes: With at most one child in its top, left, right, bottom, and center positions. Row 4. Layout Container: Grid Pane. Lays out its children nodes: In a grid of rows and columns. A child can span more than one row or column. Row 5. Layout Container: Stack Pane. Lays out its children nodes: In a front to back stack.

The methods are in the java f x dot scene dot control package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: String. Method name and argument list: get Text, left parentheses, right parentheses, returns the text typed into the Text Field. Row 2. Return value: void. Method name and argument list: set Text, left parentheses, String new Text, right parentheses, sets the text in the Text Field to new Text.

Back to Table

The method is in the java f x dot event package. The method has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: Object. Method name and argument list: get Source, left parentheses, right parentheses, returns the object on which the event was triggered.

The table summarizes the meaning of the element, its attributes, the annotation and the prefixes of F X M L. The row entries are as follows. Row 1. F X M L Element: f x colon define. Meaning: Used to create objects not in the scene graph that need to be referenced later. Row 2. F X M L Attributes: f x colon i d. Meaning: Defines a name that can be referenced across the F X M L application. Row 3. F X M L Attributes: f x colon controller. Meaning: Defines a class that contains event handling code for one or more controls. Row 4. F X M L Attributes: on Action. Meaning: Defines a method name, left parentheses, preceded by, double quotes, hash symbol, double quotes, right parentheses, in the controller that should be executed when the user interacts with the control. Row 5. F X M L Annotation: at symbol, F X M L. Meaning: Allows F X M L to access a private or protected class, method, or data. Row 6. F X M L Prefixes: hyphen f x hyphen. Meaning: Used to distinguish a Java F X style attribute from a C S S attribute. Row 7. F X M L Prefixes: dollar sign. Meaning: Used as a prefix to a variable name when the variable is used as a property value. Row 8. F X M L Prefixes: at symbol. Meaning: Used as a prefix for a U R I to specify that the path of the U R I starts with the current folder.

Back to Example

The methods are in the java f x dot scene dot image package. The constructor is as follows: Image, left parentheses, String U R L, right parentheses, constructs and Image from the file named in U R L. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: Pixel Reader. Method name and argument list: get Pixel Reader, left parentheses, right parentheses, returns a Pixel Reader object for accessing the pixels in the Image. Row 2. Return value: double. Method name and argument list: get Height, left parentheses, right parentheses, returns the height of the image in pixels. Row 3. Return value: double. Method name and argument list: get Width, left parentheses, right parentheses, returns the width of the image in pixels.

Back to Table

The method is in the java f x dot scene dot image package. The constructor is as follows: Writable Image, left parentheses, int width, comma, int height, right parentheses, constructs an empty Writable Image of the specified width and height. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: Pixel Writer. Method name and argument list: get Pixel Writer, left parentheses, right parentheses, returns a Pixel Writer object for writing the pixels in the image.

Back to Table

The method is in the java f x dot scene dot image package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: Color. Method name and argument list: get Color, left parentheses, int x, comma, int y, right parentheses, returns the Color of the pixel at coordinate, left parentheses, x, comma, y, right parentheses, in the image.

Back to Table

The method is in the java f x dot scene dot image package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: void. Method name and argument list: set Color, left parentheses, int x, comma, int y, comma, Color c, right parentheses, sets the pixel at coordinate, left parentheses, x, comma, y, right parentheses, to the color c.

Back to Table

The methods are in the java f x dot scene dot paint package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: double. Method name and argument list: get Red, left parentheses, right parentheses, returns the red component of the color in the range 0.0 to 1.0. Row 2. Return value: double. Method name and argument list: get Green, left parentheses, right parentheses, returns the green component of the color in the range 0.0 to 1.0. Row 3. Return value: double. Method name and argument list: get Blue, left parentheses, right parentheses, returns the blue component of the color in the range 0.0 to 1.0. Row 4. Return value: Color. Method name and argument list: gray, left parentheses, double value, right parentheses, returns a Color object where the red, green, and blue components are set to value, which can range from 0.0 to 1.0.

Back to Table

Back to Example

The methods are in the java f x dot scene dot control package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: double. Method name and argument list: get Value, left parentheses, right parentheses, returns the current value of the Slider as a double. Row 2. Return value: Double Property. Method name and argument list: value Property, left parentheses, right parentheses, returns the current value of the Slider as a Double Property which is a Property wrapper class for a double, and implements the Observable Value, left angled bracket, Number, right angled bracket, interface.

Back to Table

The method is in the java f x dot beans dot value package. The row entry is as follows. Return value: void. Method name and argument list: changed, left parentheses, Observable Value, left angled bracket, question mark, extends uppercase t, right angled bracket, observable, comma, uppercase t, old Value, comma, uppercase t, new Value, right parentheses, The Change Listener must implement this method to handle changes to the Observable Value.

Back to Table

The method is in the java dot lang package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: double. Method name and argument list: double Value, left parentheses, right parentheses, abstract method in the Number class overridden by the Double class, semicolon, it returns the value of a Double object as a double.

Back to Table

The methods are in the java f x dot beans dot value package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: add Listener, left parentheses, Change Listener, left angled bracket, question mark, super, uppercase t, right angled bracket, listener, right parentheses, adds a Change Listener whose code will execute whenever the value of the Observable Value changes. Row 2. Return value: uppercase t. Method name and argument list: get Value, left parentheses, right parentheses, returns the current value of the Observable Value object. Row 3. Return value: void. Method name and argument list: remove Listener, left parentheses, Change Listener, left angled bracket, question mark, super, uppercase t, right angled bracket, listener, right parentheses, removes the listener so that it is no longer notified of changes to the value of the Observable Value.

Back to Table

Back to Example

The methods are in the java f x dot scene dot layout package. The row entries are as follows. Row 1. Return value: void. Method name and argument list: add, left parentheses, Node child, comma, int column Index, comma, int row Index, right parentheses, adds child to this Grid Pane at row row Index and column column Index. Row 2. Return value: Observable List, left angled bracket, Row Constraints, right angled bracket. Method name and argument list: get Row Constraints, left parentheses, right parentheses, returns a list of row constraints for this Grid Pane. Row 3. Return value: Observable List, left angled bracket, Column Constraints, right angled bracket. Method name and argument list: get Column Constraints, left parentheses, right parentheses, returns a list of column constraints for this Grid Pane.

Back to Table

The methods are in the java dot util package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: boolean. Method name and argument list: add, left parentheses, uppercase e, lowercase e, right parentheses, appends lowercase e to the end of the list. Row 2. Return value: void. Method name and argument list: clear, left parentheses, right parentheses, removes all the elements from the list.

Back to Table

The method is in the java f x dot scene dot layout package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: void. Method name and argument list: set Percent Height, left parentheses, double value, right parentheses, sets the height of a row as a percentage of the total height of the Grid Pane.

Back to Table

The method is in the java f x dot scene dot layout package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: void. Method name and argument list: set Percent Width, left parentheses, double value, right parentheses, sets the width of a column as a percentage of the total width of the Grid Pane.

Back to Table

The methods are in the java f x dot scene dot control package. The constructor is as follows: Button, left parentheses, right parentheses, creates an empty Button. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: set Style, left parentheses, String style, right parentheses, sets the value of the style property of this Button to style, which is expected to be a C S S like string. This method is inherited from Node. Row 2. Return value: void. Method name and argument list: set Max Width, left parentheses, double value, right parentheses, sets the value of the max Width property of this Button to value. This method is inherited from Region. Row 3. Return value: void. Method name and argument list: set Max Height, left parentheses, double value, right parentheses, sets the value of the max Height property of this Button to value. This method is inherited from Region. Row 4. Return value: void. Method name and argument list: set On Action, left parentheses, Event Handler, left angled bracket, Action Event, right angled bracket, handler, right parentheses, registers handler as the event handler for this Button. When the button is clicked, the handle method of handler's class will be called automatically. This method is inherited from Button Base.

Back to Example

The method is in the java f x dot scene dot layout package. The table has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: Observable List, left angled bracket, Node, right angled bracket. Method name and argument list: get Children, left parentheses, right parentheses, returns the children of this pane as an Observable List of Nodes.

Back to Table

The methods are in the java f x dot scene dot control package. The constructor is as follows: Alert, left parentheses, Alert dot Alert Type type, right parentheses, constructs an Alert of type type. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: set Title, left parentheses, String title, right parentheses, sets the title of this dialog box. Row 2. Return value: void. Method name and argument list: set Header Text, left parentheses, String message, right parentheses, sets the text to display in the header of this dialog box. If message is the empty String, no space is allocated for the header and the dialog box will be smaller. Row 3. Return value: void. Method name and argument list: set Content Text, left parentheses, String message, right parentheses, sets the text to display inside dialog box. Row 4. Return value: Optional, left angled bracket, uppercase r, right angled bracket. Method name and argument list: show And Wait, left parentheses, right parentheses, shows this dialog box and waits for the user's response.

The methods are in the java f x dot animation package. The table listing the comon methods of animation subclasses has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: play, left parentheses, right parentheses, plays the animation from its current position. Row 2. Return value: void. Method name and argument list: set Auto Reverse, left parentheses, boolean value, right parentheses, if value is true, animation reverses on alternate cycles; if false, animation repeats from start position on each cycle. Row 3. Return value: void. Method name and argument list: set Cycle Count, left parentheses, int value, right parentheses, sets the animation to execute value times; if set to Animation. INDEFINITE, animation will run until stopped. Row 4. Return value: void. Method name and argument list: set On Finished, left parentheses, Event Handler, left angled bracket, Action Event, right angled bracket, handler, right parentheses, registers event handler's code to run when the animation finishes. Row 5. Return value: void. Method name and argument list: stop, left parentheses, right parentheses, stops the animation, if playing.

Line 147, indented thrice: combine Button dot set Disable, left parentheses, mode, right parentheses, semicolon. Line 148, indented once: right brace. Line 149: right brace.

Back to Example

The methods are in the java f x dot animation package. The constructor of the Fade Transition class is as follows: Fade Transition, left parentheses, Duration time, comma, Node node, right parentheses, creates a Fade Transition that will animate node for a duration of time. The table listing the selected methods of the Fade Transition class has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: set From Value, left parentheses, double opacity, right parentheses, sets the beginning opacity of the animation; the opacity can range from 0.1, fully opaque, to 0.0, fully transparent. Row 2. Return value: void. Method name and argument list: set To Value, left parentheses, double opacity, right parentheses, sets the ending opacity of the animation; the opacity can range from 1.0, fully opaque, to 0.0, fully transparent.

Back to Table

The methods are in the java dot util package. The table has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1.

Return value: Duration. Method name and argument list: millis, left parentheses, double m s, right parentheses, creates a Duration object for m s milliseconds. Row 2. Return value: Duration. Method name and argument list: seconds, left parentheses, double s e c s, right parentheses, creates a Duration object for s e c s seconds. Row 3. Return value: Duration. Method name and argument list: minutes, left parentheses, double m i n s, right parentheses, creates a Duration object for m i n s minutes. Row 4. Return value: Duration. Method name and argument list: hours, left parentheses, double h r s, right parentheses, creates a Duration object for h r s hours.

Back to Table

The method is in the java f x dot event package. The method has 2 columns labeled Return value and Method name and argument list. The row entry is as follows. Return value: void. Method name and argument list: handle, left parentheses, uppercase t event, right parentheses, provides code to run when event occurs on a registered control.

Back to Table

The methods are in the java f x dot scene dot media package. The Audio Clip constructor is as follows: Audio Clip, left parentheses, String source, right parentheses, loads an audio clip from the U R L represented by source.

The table listing the selected methods of the Audio Clip Class has 2 columns labeled Return value and Method name and argument list. The row entries are as follows. Row 1. Return value: void. Method name and argument list: set Cycle Count, left parentheses, int count, right parentheses, count is the number of times to play the sound. Row 2. Return value: void. Method name and argument list: play, left parentheses, right parentheses, plays the sound. Row 3. Return value: void. Method name and argument list: stop, left parentheses, right parentheses, stops the sound, if playing.

Back to Table

A table detailing a constructor and methods of the Rotate Transition class. Rotate Transition class belongs to the java f x dot animation package. Constructor. Rotate Transition, left parenthesis, Duration, time, comma, Node, node, right parenthesis, creates a Rotate Transition that will animate node for a duration of time. A table with selected methods of the Rotate Transition class. The table has 3 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set From Angle, left parenthesis, double, start Angle, right parenthesis, sets the angle from which to begin the rotation. Row 2: Return value, void; Method name and argument list, set To Angle, left parenthesis, double, end Angle, right parenthesis, sets the angle at which to end the rotation. Row 3: Return value, void; Method name and argument list, set By Angle, left parenthesis, double, angle, right parenthesis, sets the angle relative to the start at which to stop.

Back to Table

A table detailing a constructor and method of the Scale Transition class. Scale Transition class belongs to the java f x dot animation package. Constructor. Scale Transition, left parenthesis, Duration, time, comma, Node, node, right parenthesis, creates a Scale Transition that will animate node for a duration of time. A table with selected methods of the Scale Transition class. The table has 2 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. The row details are the following. Row 1: Return value, void; Method name and argument list, set To X, left parenthesis, double, value, right parenthesis, sets the x scale at which to stop. Row 2: Return value, void; Method name and argument list, set To Y, left parenthesis, double, value, right parenthesis, sets the y scale at which to stop.

Back to Table

A table detailing the constructor of the Sequential Transition class. Sequential Transition belongs to the java f x dot animation package. Constructor. Sequential Transition, left parenthesis, Animation, dot, dot, dot, children, right parenthesis, creates a Sequential Transition that will play all children animations in sequence.

Back to Table

A table detailing a constructor and method of the Translate Transition class. Translate Transition belongs to the java x dot animation package. Constructor. Translate Transition, left parenthesis, Duration, time, comma, Node node, right parenthesis, creates a Translate Transition that will animate node for a duration of time. A table detailing selected methods of the Translate Transition class. The table has 4 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set From X, left parenthesis, double, value, right parenthesis, sets the starting x value. Row 2: Return value, void; Method name and argument list, set To X, left parenthesis, double, value, right parenthesis, sets the ending x value. Row 3: Return value, void; Method name and argument list, set From Y, left parenthesis, double, value, right parenthesis, sets the starting y value. Row 4: Return value, void; Method name and argument list, set To Y, left parenthesis, double, value, right parenthesis, sets the ending y value.

Back to Table

A table detailing a constructor of the Parallel Transition class. Parallel Transition class belongs to the java f x dot animation package. Parallel Transition, left parenthesis, Animation, dot, dot, dot, children, right parenthesis, creates a Parallel Transition that will play all children animations simultaneously.

Back to Table

Code in the program Animation Sampler dot java. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Animation Sampler. Line 2: demonstrates various animations. Line 3: Anderson, comma, Franceschi. Line 4: Asterisk, forward slash. Line 5: Blank. Line 6: import, java, dot, net, dot, U R L, semicolon. Line 7: import, java f x, dot, application, dot, asterisk, semicolon. Line 8: import, java f x, dot, f x m l, dot, asterisk, semicolon. Line 9: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 10: import, java f x, dot, scene, dot, asterisk, semicolon. Line 11: import, java f x, dot, stage, dot, asterisk, semicolon. Line 12: Blank. Line 13: public, class, Animation Sampler, extends, Application. Line 14: Left brace. Line 15, indented once: at, Override. Line 16, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis, forward slash, forward slash, throws Exception. Line 17, indented once: Left brace. Line 18, indented twice: try. Line 19, indented twice: Left brace. Line 20, indented 3 times: U R L, u r l, equals. Line 21, indented 4 times: get Class, left parenthesis, right parenthesis, dot, get Resource, left parenthesis, open quotes, f x m l underscore animation dot f x m l, close quotes, right parenthesis, semicolon. Line 22, indented 3 times: Border Pane, root, equals, F X M L Loader, dot, load, left parenthesis, u r l, right parenthesis, semicolon. Line 23, indented 3 times: Scene, scene, equals, new, Scene, left parenthesis, root, comma, 800, comma, 600, right parenthesis, semicolon. Line 24, indented 3 times: stage, dot, set Title, left parenthesis, open quotes, Animation Sampler, close quotes, right parenthesis. Line 25, indented 3 times: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Line 26, indented 3 times: stage, dot, show, left parenthesis, right parenthesis, semicolon. Line 27, indented twice: right brace. Line 28, indented twice: catch, left parenthesis, Exception, e, right parenthesis. Line 29, indented twice: Left brace. Line 30, indented 3 times: e, dot, print Stack Trace, left parenthesis, right parenthesis, semicolon. Line 31, indented twice: right brace. Line 32, indented once: right brace. Line 33: Blank. Line 34, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 35, indented once: Left brace. Line 36, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 37, indented once: right brace. Line 38: right brace.

Line 63, indented once: Forward slash, asterisk, asterisk, get Number Of Colors method. Line 64, indented once: Asterisk, at, return, length of coloring Colors. Line 65, indented once: Asterisk, forward slash. Line 66, indented once: public, i n t, get Number Of Colors, left parenthesis, right parenthesis. Line 67, indented once: Left brace. Line 68, indented twice: return, coloring Colors, dot, length, semicolon. Line 69, indented once: right brace. Line 70: Blank. Line 71, indented once: Forward slash, asterisk, asterisk, get Grid Hex Color method. Line 72, indented once: Asterisk, at, param, row, an i n t, the row index. Line 73, indented once: Asterisk, at, param c o l, an i n t, the column index. Line 74, indented once: Asterisk, at, return a String, the hex equivalent of grid Color, left square brace, row, right square brace, left square brace, c o l, right square brace. Line 75, indented once: Asterisk, forward slash. Line 76, indented once: public, String, get Grid Hex Color, left parenthesis, i n t, row, comma, i n t, c o l, right parenthesis. Line 77, indented once: Left brace. Line 78, indented twice: String, color Text, equals, open quotes, hash, close quotes. Line 79, indented 3 times: plus, to Hex, left parenthesis, left parenthesis, i n t, right parenthesis, left parenthesis, 255, asterisk, grid Colors, left square brace, row, right square brace, left square brace, c o l, right square brace, dot, get Red, left parenthesis, right parenthesis, right parenthesis, right parenthesis. Line 80, indented 3 times: plus, to Hex, left parenthesis, left parenthesis, i n t, right parenthesis, left parenthesis, 255, asterisk, grid Colors, left square brace, row, right square brace, left square brace, c o l, right square brace, dot, get Green, left parenthesis, right parenthesis, right parenthesis, right parenthesis. Line 81, indented 3 times: plus, to Hex, left parenthesis, left parenthesis, i n t, right parenthesis, left parenthesis, 255, asterisk, grid Colors, left square brace, row, right square brace, left square brace, c o l, right square brace, dot, get Blue, left parenthesis, right parenthesis, right parenthesis, right parenthesis, semicolon. Line 82, indented twice: return, color Text, semicolon. Line 83, indented once: right brace. Line 84: Blank. Line 85, indented once: forward slash, asterisk, asterisk, to Hex method. Line 86, indented once: Asterisk, at, return, a String, the Hex equivalent of color Intensity. Line 87, indented once: Asterisk, forward slash. Line 88, indented once: public, String, to Hex, left parenthesis, i n t, color Intensity, right parenthesis. Line 89, indented once: Left brace. Line 90, indented twice: if, left parenthesis, color Intensity, greater than, 255, right parenthesis. Line 91, indented 3 times: color Intensity, equals, 255, semicolon. Line 92, indented twice: else, if, left parenthesis, color Intensity, less than, 0, right parenthesis. Line 93, indented 3 times: color Intensity, equals, 0, semicolon. Line 94: Blank. Line 95, indented twice: i n t, first Digit, equals, color Intensity, forward slash, 16, semicolon. Line 96, indented twice: i n t, second Digit, equals, color Intensity, percentage, 16, semicolon. Line 97, indented twice: return, String, dot, value Of, left parenthesis, hex Digits, left square brace, first Digit, right square brace, right parenthesis, plus, hex Digits, left square brace, second Digit, right square brace, semicolon. Line 98, indented once: right brace. Line 99: Blank. Line 100, indented once: Forward slash, asterisk, asterisk, highest Count method. Line 101, indented once: Asterisk, at return, the highest color frequency in the grid. Line 102: Asterisk, forward slash. Line 103, indented once: public, i n t, highest Count, left parenthesis, right parenthesis. Line 104, indented once: Left brace. Line 105, indented twice: i n t, max, equals, counts, left square brace, 0, right square brace, semicolon. Line 106, indented twice: for, left square brace, i n t, i, equals, 1, semicolon, i, less than, counts, dot, length, semicolon, i, plus, plus, right parenthesis. Line 107, indented twice: Left brace. Line 108, indented 3 times: if, left parenthesis, counts, left square brace, i, right square brace, greater than, max, right parenthesis. Line 109, indented 4 times: max, equals, counts, left square brace, i, right square brace, semicolon. Line 110, indented twice: right brace. Line 111, indented twice: return, max, semicolon. Line 112, indented once: right brace. Line 113: Blank. Line 114, indented once: Forward slash, asterisk, asterisk, is Correct method. Line 115, indented once: Asterisk, @, param, index, the index in the coloring Colors array to check. Line 116, indented once: Asterisk, at, return true if the frequency of the color for index. Line 117, indented once: Asterisk, is the highest, false otherwise. Line 118, indented once: Asterisk, forward slash. Line 119, indented once: public, boolean, is Correct, left parenthesis, i n t, index, right parenthesis. Line 120, indented once: Left brace. Line 121, indented twice: return, counts, left square brace, index, right square brace, equals, equals, highest Count, left parenthesis, right parenthesis, semicolon. Line 122, indented once: right brace. Line 123: Blank. Line 124, indented once: forward slash, asterisk, asterisk, get Title method. Line 125, indented once: Asterisk, at, return, a String representing a title for this object. Line 126, indented once: Asterisk, forward slash. Line 127, indented once: public, String, get Title, left parenthesis, right parenthesis. Line 128, indented once: Left brace. Line 129, indented twice: return, open quotes, What is the most frequent color, question mark, close quotes, semicolon. Line 130, indented once: right brace. Line 131: Blank. Line 132, indented once: Forward slash, asterisk, asterisk, get Label method. Line 133, indented once: Asterisk, at, param, index, comma, the index of the Color name. Line 134, indented once: Asterisk, at, return the color name. Line 135, indented once: asterisk, forward slash. Line 136, indented once: public, String, get Label, left parenthesis, i n t, index, right parenthesis. Line 137, indented once: left brace. Line 138, indented twice: return, labels, left square brace, index, right brace, semicolon. Line 139, indented once: right brace. Line 140: Blank. Line 141, indented once: Forward slash, asterisk,

asterisk, get Index method. Line 142, indented once: Asterisk, at, param label, a color name in the labels array. Line 143, indented once: Asterisk, at, return index of the color name in the labels array. Line 144, indented once: Asterisk, forward slash. Line 145, indented once: public, i n t, get Index, left parenthesis, String, label, right parenthesis. Line 146, indented once: Left brace. Line 147, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, labels, dot, length, semicolon, i, plus, plus, right parenthesis. Line 148, indented twice: Left brace. Line 149, indented 3 times: if, left parenthesis, labels, left square brace, i, right square brace, dot, equals, left parenthesis, label, right parenthesis, right parenthesis. Line 150, indented 4 times: return, i, semicolon. Line 151, indented twice: right brace. Line 152, indented twice: return, minus 1, semicolon. Line 153, indented once: right brace. Line 154: right brace.

Line 46, indented 4 times: labels, left square brace, i, right square brace, left square brace, j, right square brace, dot, set Max Width, left parenthesis, Double, dot, MAX underscore VALUE, right parenthesis, semicolon. Line 47, indented 4 times: labels, left square brace, i, right square brace, left square brace, j, right square brace, dot, set Max Height, left parenthesis, Double, dot, MAX underscore VALUE, right parenthesis, semicolon. Line 48, indented 4 times: grid, dot, add, left parenthesis, labels, left square brace, i, right square brace, left square brace, j, right square brace, comma, j, comma, i, right parenthesis, semicolon. Line 49, indented 3 times: right brace. Line 50, indented twice: right brace. Line 51: Blank. Line 52, indented twice: button Panel, equals, new, V Box, left parenthesis, right parenthesis, semicolon. Line 53: Blank. Line 54, indented twice: buttons, equals, new, Button, left square brace, number Of Buttons, right square brace, semicolon. Line 55, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, buttons, dot, length, semicolon, i, plus, plus, right brace. Line 56, indented twice: left brace. Line 57, indented 3 times: buttons, left square brace, i, right square brace, equals, new, Button, left parenthesis, right parenthesis, semicolon. Line 58, indented 3 times: forward slash, forward slash, make button fill up available width and height. Line 59, indented 3 times: buttons, left square brace, i, right square brace, dot, set Max Width, left parenthesis, Double, dot, MAX underscore VALUE, right parenthesis, semicolon. Line 60, indented 3 times: buttons, left square brace, i, right square brace, dot, set Max Height, left parenthesis, Double, dot, MAX underscore VALUE, right parenthesis, semicolon. Line 61, indented 3 times: V Box, dot, set V grow, left parenthesis, buttons, left square brace, i, right square brace, comma, Priority, dot, ALWAYS, right parenthesis, semicolon. Line 62, indented 3 times: button Panel, dot, get Children, left parenthesis, right parenthesis, dot, add, left parenthesis, buttons, left square brace, i, right square brace, right parenthesis, semicolon. Line 63, indented twice: right brace. Line 64: Blank. Line 65, indented twice: set Left, left parenthesis, button Panel, right parenthesis, semicolon. Line 66, indented twice: set Center, left parenthesis, grid, right parenthesis, semicolon. Line 67, indented once: right brace. Line 68: Blank. Line 69, indented once: public, void, set Button Text, left parenthesis, i n t, row, comma, String, text, right parenthesis. Line 70, indented once: Left brace. Line 71, indented twice: buttons, left brace, row, right brace, dot, set Text, left parenthesis, text, right parenthesis, semicolon. Line 72, indented once: right brace. Line 73: Blank. Line 74, indented once: public, void, set Button

Listener, left parenthesis, i n t, row, comma, Event Handler, left angle bracket, Action Event, right angle bracket, e h, right parenthesis. Line 75, indented once: Left brace. Line 76, indented once: buttons, left square brace, row, right square brace, dot, set On Action, left parenthesis, e h, right parenthesis, semicolon. Line 77, indented once: right brace. Line 78: Blank. Line 79, indented once: public, void, set Label Background, left parenthesis, i n t, row, comma, i n t, c o l, comma, String, hex Color, right parenthesis. Line 80, indented once: Left brace. Line 81, indented twice: labels, left square brace, row, right square brace, left square brace, c o l, right square brace, dot, set Style, left parenthesis, open quotes, hyphen f x hyphen background hyphen color, colon, close quotes, plus, hex Color, right parenthesis, semicolon. Line 82, indented once: right brace. Line 83: right brace.

Back to Example

A table detailing the set V grow method of the V Box class. The V Box class belongs to the java f x dot scene dot layout package. Return value: void. Method name and argument list: set V grow, left parenthesis, Node, child, comma, Priority, value, right parenthesis, static method that sets the vertical grow priority of child, assuming that child is contained in a V Box. If set, the V Box will allocate additional space for child if space is available.

Table detailing useful classes and methods for mouse and touch events. The package is java f x dot scene dot input. A table detailing methods of the Mouse Event class. The table has 4 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. Row 1: Return value, double; Method name and argument list, get Scene X, left parenthesis, right parenthesis, returns the x coordinate of this Mouse Event in the Scene where it occurs. Row 2: Return value, double; Method name and argument list, get Scene Y, left parenthesis, right parenthesis, returns the y coordinate of this Mouse Event in the Scene where it occurs. Row 3: Return value, double; Method name and argument list, get X, left parenthesis, right parenthesis, returns the x coordinate of the Mouse Event relative to the node on which the mouse listener is registered. Row 4: Return value, double; Method name and argument list, get Y, left parenthesis, right parenthesis, returns the y coordinate of the Mouse Event relative to the node on which the mouse listener is registered. Method of the Touch Event class. Return value: Touch Point. Method name and argument list: get Touch Point, left parenthesis, right parenthesis, returns the touch point for this Touch Event. Table detailing methods of the Touch Point class. The table has

4 rows and 4 columns. It has the following column headings. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, double; Method name and argument list, get Scene X, left parenthesis, right parenthesis, returns the x coordinate of this Touch Point in the Scene in which it occurs. Row 2: Return value, double; Method name and argument list, get Scene Y, left parenthesis, right parenthesis, returns the y coordinate of this Touch Point in the Scene in which it occurs. Row 3: Return value, double; Method name and argument list, get X, left parenthesis, right parenthesis, returns the x coordinate of the Touch Point relative to the node on which the touch listener is registered. Row 4: Return value, double; Method name and argument list, get Y, left parenthesis, right parenthesis, returns the y coordinate of the Touch Point relative to the node on which the touch listener is registered.

Back to Table

A table detailing the handle method of the Event Handler, left angle bracket, T extends Event, right angle bracket interface. void handle, left parenthesis, T, event, right parenthesis. This method is called when an event occurs for which this handler is registered.

Back to Table

A table detailing useful methods of the Node class for mouse and touch events. The table has 4 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. The row details in the table are the following. Row 1: Return value, void; Method name and argument list, set On Mouse Pressed, left parenthesis, Event Handler, left angle bracket, question mark, super, Mouse Event, right angle bracket, handler, right parenthesis, registers handler as the listener to execute when the user presses the mouse. A parameter of null removes any previously registered handler. Row 2: Return value, void; Method name and argument list, set On Mouse Moved, left parenthesis, Event Handler, left angle bracket, question mark, super, Mouse Event, right angle bracket, handler, right parenthesis, registers handler as the listener to execute when the user moves the mouse. A parameter of null removes any previously registered handler. Row 3: Return value, void; Method name and argument list, set On Touch Pressed, left parenthesis, Event Handler, left angle bracket, question mark, super, Touch Event, right angle bracket, handler, right parenthesis, registers handler as the listener to execute when the user touches the screen. A parameter of null removes any previously registered handler. Row 4: Return value, void; Method name and argument list, set On Touch Moved, left parenthesis, Event Handler, left angle bracket, question mark, super, Touch Event, right angle bracket, handler, right parenthesis, registers handler as the listener to execute when the user moves the touch point on the screen. A parameter of null removes any previously registered handler.

Code in the Treasure Hunt class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Treasure Hunt class. Line 2: Asterisk, Anderson, comma Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java, dot, util, dot, Random, semicolon. Line 6: import, java f x, dot, scene, dot, canvas, dot, Graphics Context, semicolon. Line 7: import, java f x, dot, scene, dot, paint, dot, Color, semicolon. Line 8: import, java f x, dot, scene, dot, text, dot, Font, semicolon. Line 9: Blank. Line 10: public, class, Treasure Hunt. Line 11: Left brace. Line 12, indented once: public, static, i n t, DEFAULT underscore GAME underscore SIZE, equals, 300, semicolon, forward slash, forward slash, side of window. Line 13, indented once:

public, static, i n t, SIDE, equals, 40, semicolon, forward slash, forward slash, side of treasure. Line 14: Blank. Line 15, indented once: private, i n t, game Size, semicolon. Line 16, indented once: private, i n t, x C t r, semicolon, forward slash, forward slash, x coordinate of center of treasure. Line 17, indented once: private, i n t, y C t r, semicolon, forward slash, forward slash, y coordinate of center of treasure. Line 18, indented once: private, String, status, equals, open quotes, close quotes, semicolon, forward slash, forward slash, message. Line 19, indented once: private, boolean, game Over, equals, false, semicolon. Line 20: Blank. Line 21, indented once: forward slash, asterisk, asterisk, Constructor. Line 22, indented once: Asterisk, at, param game Size the size of the game. Line 23: Asterisk, forward slash. Line 24, indented once: public, Treasure Hunt, left parenthesis, i n t, game Size, right parenthesis. Line 25, indented once: Left brace. Line 26, indented twice: if, left parenthesis, game Size, greater than, SIDE, right parenthesis. Line 27, indented 3 times: this, dot, game Size, equals, game Size, semicolon. Line 28, indented twice: else. Line 29, indented 3 times: this, dot, game Size, equals, DEFAULT underscore GAME underscore SIZE, semicolon. Line 30, indented twice: Forward slash, forward slash, generate treasure center. Line 31, indented twice: Random, random, equals, new, Random, left parenthesis, right parenthesis, semicolon. Line 32, indented twice: x C t r, equals, SIDE, forward slash, 2, plus, plus, random, dot, next I n t, left parenthesis, this, dot, game Size, minus, SIDE, right parenthesis, semicolon. Line 33, indented twice: y C t r, equals, SIDE, forward slash, 2, plus, random, dot, next Int, left parenthesis, this, dot, game Size, minus, SIDE, right parenthesis, semicolon. ll. Line 34, indented once: right brace. Line 35: Blank. Line 36, indented once: Forward slash, asterisk, asterisk, get Game Size accessor. Line 37, indented once: Asterisk, at, return game Size. Line 38, indented once: Asterisk, forward slash. Line 39, indented once: public, i n t, get Game Size, left parenthesis, right parenthesis. Line 40, indented once: Left brace. Line 41, indented twice: return, game Size, semicolon. Line 42, indented once: right brace. Line 43: Blank. Line 44, indented once: Forward slash, asterisk, asterisk, is Game Over method. Line 45, indented once: Asterisk, at, return game Over. Line 46, indented once: Asterisk, forward slash. Line 47, indented once: public, boolean, is Game Over, left parenthesis, right parenthesis. Line 48, indented once: Left brace. Line 49, indented twice: return, game Over, semicolon. Line 50, indented once: right brace. Line 51: Blank. Line 52, indented once: Forward slash, asterisk, asterisk, play method. Line 53, indented once: Asterisk, at, param, x, the x coordinate of the play. Line 54, indented once: Asterisk, at, param, y, the y coordinate of the play. Line 55, indented once: Asterisk, forward slash. Line 56, indented once: public, void, play, left parenthesis, i n t, x, comma, i n t, y, right parenthesis. Line 57, indented once: Left brace. Line 58, indented twice: forward slash, forward slash, is mouse within treasure, question mark. Line 59, indented twice: if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, SIDE, forward slash, 2. Line 60, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, SIDE, forward slash, 2, right parenthesis. Line 61, indented twice: Left brace. Line 62, indented 3 times: game Over, equals, true, semicolon. Line 63, indented 3 times: status, equals, open quotes, Found, close quotes, semicolon. Line 64, indented twice: right brace. Line 65, indented twice: forward slash, forward slash, is mouse within half-length of the treasure, question mark. Line 66, indented twice: else, if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, left parenthesis, 1.5, asterisk, SIDE, right parenthesis. Line 67, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, left parenthesis, 1.5, asterisk, SIDE, right parenthesis, right parenthesis. Line 68, indented 3 times: status, equals, open quotes, Hot, close quotes, semicolon. Line 69, indented twice: forward slash, forward slash, is mouse within 1 length of the treasure, question mark. Line 70, indented twice: else, if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, left parenthesis, 2, asterisk, SIDE, right parenthesis. Line 71, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, left parenthesis, 2, asterisk, SIDE, right parenthesis, right parenthesis. Line 72, indented 3 times: status, equals, open quotes, Warm, close quotes, semicolon. Line 73, indented twice: forward slash, forward slash, is mouse within 2 lengths of the treasure, question mark. Line 74, indented twice: else, if, left parenthesis, Math, dot, a b s, left parenthesis, x, minus, x C t r, right parenthesis, less than, left parenthesis, 3, asterisk, SIDE, right parenthesis. Line 75, indented a few times: ampersand, ampersand, Math, dot, a b s, left parenthesis, y, minus, y C t r, right parenthesis, less than, left parenthesis, 3, asterisk, SIDE, right parenthesis, right parenthesis. Line 76, indented 3 times: status, equals, open quotes, Lukewarm, close quotes, semicolon. Line 77, indented twice: else, forward slash, forward slash, mouse is not near treasure. Line 78, indented 3 times: status, equals, open quotes, Cold, close quotes, semicolon. Line 79, indented once: right brace. Line 80: Blank. Line 81, indented once: forward slash, asterisk, asterisk, draw method. Line 82, indented once: Asterisk, at, param, g c a Graphics Context reference. Line 83, indented once: Asterisk, at, param, x, the x coordinate of the play. Line 84, indented once: Asterisk, at, param, y, the y coordinate of the play. Line 85, indented once: Asterisk, forward slash. Line 86, indented once: public, void, draw, left parenthesis, Graphics Context, g c, comma, i n t, x, comma, i n t, y, right parenthesis. Line 87, indented once: Left brace. Line 88, indented twice: g c, dot, set Fill, left parenthesis, Color, dot, BLUE, right parenthesis, semicolon. Line 89, indented twice: g c, dot, set Font, left parenthesis, new, Font, left parenthesis, 24, right parenthesis, right parenthesis, semicolon. Line 90, indented twice: g c, dot, clear Rect, left parenthesis, 0, comma, 0, comma, game Size, comma, game Size, right parenthesis, semicolon. Line 91, indented twice: if, left parenthesis, status, dot, equals, left parenthesis, open quotes, Found, close quotes, right parenthesis, right parenthesis, forward slash, forward slash, if found, draw treasure. Line 92, indented twice: Left brace. Line 93, indented 3 times: g c, dot, set Font, left parenthesis, new, Font, left parenthesis, 16, right parenthesis, right parenthesis, semicolon. Line 94, indented 3 times: g c, dot, set Fill, left parenthesis, Color, dot, RED, right parenthesis, semicolon. Line 95, indented 3 times: g c, dot, fill Rect, left parenthesis, x C t r, minus, SIDE, forward slash, 2, comma, y C t r, minus, SIDE, forward slash, 2, comma, SIDE, comma, SIDE, right parenthesis, semicolon. Line 96, indented 3 times: g c, dot, set Fill, left parenthesis, Color, dot, GREEN, right parenthesis, semicolon. Line 97, indented 3 times: g c, dot, fill Text, left parenthesis, open quotes, dollar, dollar, dollar, close quotes, comma, x C t r, minus, SIDE, forward slash, 3, comma, y C t r, plus, SIDE, forward slash, 6, right parenthesis, semicolon. Line 98, indented twice: right brace. Line 99, indented twice: else. Line 100, indented 3 times: g c, dot, fill Text, left parenthesis, status, comma, x, comma, y, right parenthesis, semicolon, forward slash, forward slash, display current status. Line 101, indented once: right brace. Line 102: right brace.

Code in the Treasure Hunt View Controller class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Treasure Hunt View Controller class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java f x, dot, event, dot, asterisk, semicolon. Line 6: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 7: import, java f x, dot, scene, dot, input, dot, asterisk, semicolon. Line 8: import, java f x, dot, scene, dot, canvas, dot, Canvas, semicolon. Line 9: import, java f x, dot, scene, dot, canvas, dot, Graphics Context, semicolon. Line 10: import, java f x, dot, stage, dot, Stage, semicolon. Line 11: Blank. Line 12: public, class, Treasure Hunt View Controller, extends, V Box. Line 13, indented a few times: implements, Event Handler, left angle bracket, Input Event, right angle bracket. Line 14: Left brace. Line 15, indented once: private, int width, height, semicolon. Line 16, indented once: private, Treasure Hunt, hunt, semicolon. Line 17, indented once: private, Graphics Context, g c, semicolon. Line 18: Blank. Line 19, indented once: Forward slash, asterisk, asterisk, Constructor. Line 20, indented once: Asterisk, at, param, hunt the model reference. Line 21, indented once: Asterisk, at, param, width the width of the Canvas rendering the game. Line 22, indented once: Asterisk, at, param, height the height of the Canvas rendering the game. Line 23, indented once: Asterisk, forward slash. Line 24, indented once: public, Treasure Hunt View Controller, left parenthesis, Treasure Hunt, hunt, comma, i n t, width, comma, i n t, height, right parenthesis. Line 25, indented once: Left brace. Line 26, indented twice: this, dot, hunt, equals, hunt, semicolon. Line 27, indented twice: this, dot, width, equals, width, semicolon. Line 28, indented twice: this, dot, height, equals, height, semicolon. Line 29, indented twice: Canvas, canvas, equals, new, Canvas, left parenthesis, width, comma, height, right parenthesis, semicolon. Line 30, indented twice: get Children, left parenthesis, right parenthesis, dot, add, left parenthesis, canvas, right parenthesis, semicolon. Line 31, indented twice: g c, equals, canvas, dot, get Graphics Context 2 D, left parenthesis, right parenthesis, semicolon. Line 32: Blank. Line 33, indented twice: this, dot, set On Mouse Moved, left parenthesis, this, right parenthesis, semicolon. Line 34, indented twice: this, dot, set On Touch Moved, left parenthesis, this, right parenthesis, semicolon. Line 35, indented once: right brace. Line 36: Blank. Line 37, indented once: forward slash, asterisk, asterisk, handle method. Line 38, indented once: Asterisk, at, param, event, the Input Event generated by the user. Line 39, indented once: Asterisk, forward slash. Line 40, indented once: public, void, handle, left parenthesis, Input Event, event, right parenthesis. Line 41, indented once: left brace. Line 42, indented twice: i n t, x, equals, minus, 100, comma, y, equals, minus, 100, semicolon. Line 43, indented twice: if, left parenthesis, event, dot, get Event

Type, left parenthesis, right parenthesis, equals, equals, Mouse Event, dot, MOUSE underscore MOVED, right parenthesis. Line 44, indented twice: Left brace. Line 45, indented 3 times: Mouse Event, m Event, equals, left parenthesis, Mouse Event, right parenthesis, event, semicolon. Line 46, indented 3 times: x, equals, left parenthesis, i n t, right parenthesis, m Event, dot, get Scene X, left parenthesis, right parenthesis, semicolon. Line 47, indented a 3 times: y, equals, left parenthesis, i n t, right parenthesis, m Event, dot, get Scene Y, left parenthesis, right parenthesis, semicolon. Line 48, indented twice: right brace. Line 49, indented twice: else, if, left parenthesis, event, dot, get Event Type, left parenthesis, right parenthesis, equals, equals, Touch Event, dot, TOUCH underscore MOVED, right parenthesis. Line 50, indented twice: Left brace. Line 51, indented 3 times: Touch Event, t Event, equals, left parenthesis, Touch Event, right parenthesis, event, semicolon. Line 52, indented 3 times: x, equals, left parenthesis, i n t, right parenthesis, t Event, dot, get Touch Point, left parenthesis, right parenthesis, dot, get Scene X, left parenthesis, right parenthesis, semicolon. Line 53, indented 3 times: y, equals, left parenthesis, i n t, right parenthesis, t Event, dot, get Touch Point, left parenthesis, right parenthesis, dot, get Scene Y, left parenthesis, right parenthesis, semicolon. Line 54, indented twice: right brace. Line 55: Blank. Line 56, indented twice: hunt, dot, play, left parenthesis, x, comma, y, right parenthesis, semicolon. Line 57: Blank. Line 58, indented twice: hunt, dot, draw, left parenthesis, g c, comma, x, comma, y, right parenthesis, semicolon. Line 59, indented twice: if, left parenthesis, hunt, dot, is Game Over, left parenthesis, right parenthesis, right parenthesis. Line 60, indented twice: Left brace. Line 61, indented 3 times: this, dot, set On Mouse Moved, left parenthesis, null, right parenthesis, semicolon. Line 62, indented 3 times: this, dot, set On Touch Moved, left parenthesis, null, right parenthesis, semicolon. Line 63, indented 3 times: Stage, stage, equals, left parenthesis, Stage, right parenthesis, get Scene, left parenthesis, right parenthesis, dot, get Window, left parenthesis, right parenthesis, semicolon. Line 64, indented 3 times: stage, dot, set Title, left parenthesis, open quotes, Thank you for playing, close quotes, right parenthesis, semicolon. Line 65, indented twice: right brace. Line 66, indented once: right brace. Line 67: right brace.

Back to Example

A table detailing useful Event Type constants of the Mouse Event and Touch Event classes. The table has 2 rows and 2 columns. It has the following column headings. Class. Constant. The row details in the table are the following. Row 1: Class, Mouse Event; Constant, MOUSE Underscore MOVED constant identifying a mouse move event. Row 2: Class, Touch Event; Constant, TOUCH underscore MOVED constant identifying a touch move event.

Back to Table

A table detailing useful classes and methods to retrieve the stage. The table has 2 rows and 2 columns. It has the following column headings. Class. Method. Row 1: Class, Node; Method, Scene, get Scene, left parenthesis, right parenthesis, returns the Scene containing this Node. Row 2: Class, Scene; Method, Window, get Window, left parenthesis, right parenthesis, returns the window for this Scene.

Back to Table

Code in the Play Treasure Hunt class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Play Treasure Hunt class. Line 2: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java f x, dot, application, dot, Application, semicolon. Line 6: import, java f x, dot, scene, dot, Scene, semicolon. Line 7: import, java f x, dot, stage, dot, Stage, semicolon. Line 8: Blank. Line 9: public, class, Play Treasure Hunt, extends, Application. Line 10: Left brace. Line 11, indented once: private, final, i n t, GAME underscore SIZE, equals, 500, semicolon. Line 12: Blank. Line 13, indented once: at, Override. Line 14, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis. Line 15, indented once: Left brace. Line 16, indented twice: Treasure Hunt, t h, equals, new, Treasure Hunt, left parenthesis, GAME underscore SIZE, right parenthesis, semicolon. Line 17, indented twice: Treasure Hunt View Controller, root, equals. Line 18, indented 3 times: new, Treasure Hunt View Controller, left parenthesis, t h, comma, GAME underscore SIZE, comma, GAME underscore SIZE, right parenthesis, semicolon. Line 19: Blank. Line 20, indented twice: Scene, scene, equals, new, Scene, left parenthesis, root, comma, GAME underscore SIZE, comma, GAME underscore SIZE, right parenthesis, semicolon. Line 21, indented twice: stage, dot, set Title, left parenthesis, open quotes, Play, exclamation mark, exclamation mark, close quotes, right parenthesis, semicolon. Line 22, indented twice: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Line 23, indented twice: stage, dot, show, left parenthesis, right parenthesis, semicolon. Line 24, indented once: right brace. Line 25: Blank. Line 26, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 27, indented once: left brace. Line 28, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 29, indented once: right brace. Line 30: right brace.

Back to Example

A table detailing Pie Chart dot Data and Pie Chart constructors. The package is java f x dot scene dot chart. The constructors the following. Pie Chart dot Data, left parenthesis, String, name, comma, double, value, right parenthesis, creates a Pie Chart dot Data, a slice of a Pie

Chart. The slice value is value and its label is name. Pie Chart, left parenthesis, Observable List, left angle bracket, Pie Chart dot Data, right angle bracket, data, right parenthesis, creates a Pie Chart using data as its data for all its slices.

Back to Table

The program code of an application to display a pie chart. Program code. In the code, the words in the variable names are merged. Line 1: import, java, dot, util, dot, Array List, semicolon. Line 2: import, java f x, dot, application, dot, Application, semicolon. Line 3: import, java f x, dot, collections, dot, F X Collections, semicolon. Line 4: import, java f x, dot, collections, dot, Observable List, semicolon. Line 5: import, java f x, dot, scene, dot, chart, dot, asterisk, semicolon. Line 6: import, java f x, dot, scene, dot, Scene, semicolon. Line 7: import, java f x, dot, stage, dot, Stage, semicolon. Line 8: Blank. Line 9: public, class, Monthly Budget Pie Chart, extends, Application. Line 10: Left brace. Line 11, indented once: private, String, left parenthesis, right parenthesis, categories. Line 12, indented twice: equals, left brace, open quotes, Rent, close quotes, comma, open quotes, Food, close quotes, comma, open quotes, Phone, close quotes, comma, open quotes, Entertainment, close quotes, comma, open quotes, Utilities, close quotes, right brace, semicolon. Line 13, indented once: private, double, left square brace, right square brace, expenses. Line 14, indented twice: equals, left brace, 800, comma, 450, comma, 72.50, comma, 200, comma, 90, right brace, semicolon. Line 15: Blank. Line 16, indented once: at, Override. Line 17, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis. Line 18, indented once: Left brace. Line 19, indented twice: Forward slash, forward slash, Create a Pie Chart, dot, Data of monthly expenses. Line 20, indented twice: Array List, left angle bracket, Pie Chart, dot, Data, right angle bracket, list, equals, new, Array List, left angle bracket, Pie Chart, dot, Data, right angle bracket, left parenthesis, right parenthesis, semicolon. Line 21, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, expenses, dot, length, semicolon, i, plus, plus, right parenthesis. Line 22, indented 3 times: list, dot, add, left parenthesis, new, Pie Chart, dot, Data, left parenthesis, categories, left square brace, i, right square brace, comma, expenses, left square brace, i, right square brace, right parenthesis, right parenthesis, semicolon. Line 23, indented twice: Observable List, less than, Pie Chart, dot, Data, right angle bracket, pie Chart Data. Line 24, indented 3 times: equals, F X Collections, dot, observable List, left parenthesis, list, right parenthesis, semicolon. Line 25: Blank. Line 26, indented twice: Forward slash, forward slash, Create a Pie Chart with pie Chart Data. Line 27, indented twice: Pie Chart, chart, equals, new, Pie Chart, left parenthesis, pie Chart Data, right parenthesis, semicolon. Line 28, indented twice: chart, dot, set Title, left parenthesis, open quotes, Monthly Budget, close quotes, right parenthesis, semicolon. Line

29: Blank. Line 30, indented twice: Forward slash, forward slash, Define the scene and stage. Line 31, indented twice: Scene, scene, equals, new, Scene, left parenthesis, chart, comma, 500, comma, 400, right parenthesis, semicolon. Line 32, indented twice: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Line 33, indented twice: stage, dot, set Title, left parenthesis, open quotes, Pie Chart for Monthly Expenses, close quotes, right parenthesis, semicolon. Line 34, indented twice: stage, dot, show, left parenthesis, right parenthesis, semicolon. Line 35, indented once: right brace. Line 36: Blank. Line 37, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 38, indented once: Left brace. Line 39, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 40, indented once: right brace. Line 41: right brace.

Back to Example

A table detailing the observable List method of the F X collections class. Return value: Observable, List, left angle bracket, E, right angle bracket. Method name and argument list: observable, left parenthesis, List, left angle bracket, E, right angle bracket, list, right parenthesis, constructs and returns an Observable List composed of elements of type E from list. Changes to that Observable List will be reflected in components that are registered on that Observable List.

Back to Table

Code for the Investment class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, asterisk, abstract Investment class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: public, abstract, class, Investment. Line 6: Left brace. Line 7, indented once: public, static, final, i n t, DEFAULT underscore YEARS, equals, 4, semicolon. Line 8, indented once: public, static, final, double, BEGIN underscore INVEST underscore AMOUNT, equals, 100, semicolon. Line 9, indented once: private, double, left square brace, right square brace, amounts, semicolon. Line 10, indented once: private, i n t, years, semicolon. Line 11, indented once: private, double, growth Rate, semicolon. Line 12, indented once: private, String, type, semicolon. Line 13: Blank. Line 14, indented once: Forward slash, asterisk, Constructor. Line 15, indented once: Asterisk, at, param, years, an i n t, the new value of years. Line 16, indented once: Asterisk, at, param type, a String, the new value for the investment type. Line 17, indented once: Asterisk, forward slash. Line 18, indented once: public, Investment, left parenthesis, i n t, years, comma, String, type, right parenthesis. Line 19, indented once: Left brace. Line 20, indented twice: if, left parenthesis, years, less than, 1, right parenthesis. Line 21, indented 3 times: this, dot, years, equals, DEFAULT underscore YEARS, semicolon. Line 22, indented twice:

else. Line 23, indented 3 times: this, dot, years, equals, years, semicolon. Line 24: Blank. Line 25, indented twice: amounts, equals, new, double, left square brace, this, dot, years, right square brace, semicolon. Line 26, indented twice: amounts, left square brace, 0, right square brace, equals, BEGIN underscore INVEST underscore AMOUNT, semicolon. Line 27: Blank. Line 28, indented twice: this, dot, type, equals, type, semicolon. Line 29, indented once: right brace. Line 30: Blank. Line 31, indented once: Forward slash, asterisk, get Amounts method. Line 32, indented once: Asterisk, at, return a copy of amounts, a double, left square brace, right square brace. Line 33, indented once: Asterisk, forward slash. Line 34, indented once: public, double, left square brace, right square brace, get Amounts, left parenthesis, right parenthesis. Line 35, indented once: Left brace. Line 36, indented twice: double, left square brace, right square brace, temp, equals, new, double, left square brace, amounts, dot, length, right square brace, semicolon. Line 37, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, amounts, dot, length, semicolon, i, plus, plus, right parenthesis. Line 38, indented a few times: temp, left square brace, i, right square brace, equals, amounts, left square brace, i, right square brace, semicolon. Line 39, indented twice: return, temp, semicolon. Line 40, indented once: right brace. Line 41: blank. Line 42, indented once: Forward slash, asterisk, Accessor method for years. Line 43, indented once: Asterisk, at, return number of years. Line 44, indented once: Asterisk, forward slash. Line 45, indented once: public, i n t, get Years, left parenthesis, right parenthesis. Line 46, indented once: Left brace. Line 47, indented once: return, years, semicolon. Line 48, indented once: right brace. Line 49: Blank. Line 50, indented once: Forward slash, asterisk, Accessor method for type. Line 51, indented once: Asterisk, at, return investment type. Line 52, indented once: Asterisk, forward slash. Line 53, indented once: public, String, get Type, left parenthesis, right parenthesis. Line 54, indented once: Left brace. Line 55, indented twice: return, type, semicolon. Line 56, indented once: right brace. Line 57: Blank. Line 58, indented once: Forward slash, asterisk, Accessor method for growth Rate. Line 59, indented once: Asterisk, at, return growth Rate. Line 60, indented once: Asterisk, forward slash. Line 61, indented once: public, double, get Growth Rate, left parenthesis, right parenthesis. Line 62, indented once: Left brace. Line 63, indented twice: return, growth Rate, semicolon. Line 64, indented once: right brace. Line 65: Blank. Line 66, indented once: Forward slash, asterisk, Mutator method for growth Rate. Line 67, indented once: Asterisk, at, param growth Rate, the new value for growth Rate. Line 68, indented once: Asterisk, at, return a reference to this object. Line 69, indented once: Asterisk, forward slash. Line 70, indented once: public, Investment, set Growth Rate, left parenthesis, double, growth Rate, right parenthesis. Line 71, indented once: Left brace. Line 72, indented twice: this, dot, growth Rate, equals, growth Rate, semicolon. Line 73, indented twice: return, this, semicolon. Line 74, indented once: right brace. Line 75: Blank. Line 76, indented once: forward slash, asterisk, update Amounts method. Line 77, indented once: Asterisk, updates amounts based on growth Rate. Line 78, indented once: Asterisk, forward slash. Line 79, indented once: public, void, update Amounts, left parenthesis, right parenthesis. Line 80, indented once: Left brace. Line 81, indented twice: for, left parenthesis, i n t, i, equals, 1, semicolon, i, less than, amounts, dot, length, semicolon, i, plus, plus, right parenthesis. Line 82, indented 3 times: amounts, left parenthesis, i, right parenthesis, equals, amounts, left square brace, i, minus, 1, right square brace, asterisk, left parenthesis, 1, plus, growth Rate, right parenthesis, semicolon. Line 83, indented once: right brace. Line 84: Blank. Line 85, indented once: forward slash, asterisk, update abstract method. Line 86, indented once: Asterisk, forward slash. Line 87, indented once: public, abstract, void, update, left parenthesis, right parenthesis, semicolon. Line 88: right brace.

Back to Example

Code for the Bonds class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, asterisk, Bonds class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: public, class, Bonds, extends, Investment. Line 6: Left brace. Line 7, indented once: private, final, double, BOND underscore GROWTH underscore RATE, equals, .03, semicolon. Line 8: Blank. Line 9, indented once: Forward slash, asterisk, Constructor. Line 10, indented once: Asterisk, at, param years the new number of years. Line 11, indented once: asterisk, forward slash. Line 12, indented once: public, Bonds, left parenthesis, i n t, years, right parenthesis. Line 13, indented once: Left brace. Line 14, indented twice: super, left parenthesis, years, comma, open quotes, Bonds, close quotes, right parenthesis, semicolon. Line 15, indented twice: set Growth Rate, left parenthesis, BOND underscore GROWTH underscore RATE, right parenthesis, semicolon. Line 16, indented twice: update Amounts, left parenthesis, right parenthesis, semicolon. Line 17, indented once: right brace. Line 18: Blank. Line 19, indented once: Forward slash, asterisk, update method. Line 20, indented once: Asterisk, do nothing method: Leaves the growth rate unchanged. Line 21, indented once: Asterisk, forward slash: Line 22, indented once: public, void, update, left parenthesis, right parenthesis. Line 23, indented once: Left brace. Line 24, indented twice: forward slash, forward slash, growth rate does not change. Line 25, indented once: right brace. Line 26: right brace.

Line 84: Blank. Line 85, indented 4 times: forward slash, forward slash, change data of series. Line 86, indented 4 times: current Investment Series, dot, get Data, left parenthesis, right parenthesis, dot, clear, left parenthesis, right parenthesis, semicolon. Line 87, indented 4 times: double, left square brace, right square brace, current Amounts, equals, investments, left square brace, i, right square brace, dot, get Amounts, left parenthesis, right parenthesis, semicolon. Line 88, indented 4 times: for, left parenthesis, i n t, j, equals, 0, semicolon, j, less than, current Amounts, dot, length, semicolon, j, plus, plus, right parenthesis. Line 89, indented 4 times: Left brace. Line 90, indented 5 times: current Investment Series, dot, get Data, left parenthesis, right parenthesis, dot, add, left parenthesis. Line 91, indented 6 times: new, X Y Chart, dot, Data, left angle bracket, String, comma, Number, right angle bracket, left parenthesis, open quotes, close quotes. Line 92, indented 7 times: plus, left parenthesis, starting Year, plus, j, right parenthesis, comma, current Amounts, left square bracket, j, right square bracket, right parenthesis, right parenthesis, semicolon. Line 93, indented 4 times: right brace. Line 94: Blank. Line 95, indented 4 times:

forward slash, forward slash, update series. Line 96, indented 4 times: series, dot, set, left parenthesis, i, comma, current Investment Series, right parenthesis, semicolon. Line 97, indented 3 times: right brace. Line 98, indented twice: right brace. Line 99, indented once: right brace. Line 100: Blank. Line 101, indented once: public, void, set Button Listener, left parenthesis, Event Handler, left angle bracket, Action Event, right angle bracket, e h, right parenthesis. Line 102, indented once: Left brace. Line 103, indented twice: button, dot, set On Action, left parenthesis, e h, right parenthesis, semicolon. Line 104, indented once: right brace. Line 105: right brace.

Back to Example

A table detailing a constructor of the Bar Chart class. The Bar Chart class belongs to the package java f x dot scene dot chart. Bar Chart, left parenthesis, Axis, left angle bracket, X, right angle bracket, x Axis, comma, Axis, left angle bracket, Y, right angle bracket, y Axis, right parenthesis, creates a Bar Chart with the two axes. One of the axes should be a Category Axis, the other one a Value Axis. Their order determines if the bar chart is horizontal or vertical.

Back to Table

A table detailing X Y Chart dot Series and X Y Chart dot Data constructors. The package is java f x, dot, scene, dot, chart. The constructors are the following. X Y Chart, dot, Series, left parenthesis, right parenthesis, creates an X Y Chart dot Series that will contain X Y Chart dot Data items. X Y Chart, dot, Data, left parenthesis, X, x Value, comma, Y, y Value, right parenthesis, creates data for the two axes of the chart; the X and Y types should match the X and Y types for the x and y axes.

Back to Table

A table detailing the get Data and set Name methods of the X Y Chart dot Series class. The table has 2 rows and 2 columns. It has the following column headings. Return value. Method name and argument list. The row details are the following. Row 1: Return value, Observable List, left angle bracket, X Y Chart, dot, Data, left angle bracket, X, comma, Y, right angle bracket, right angle bracket; Method name and argument list, get Data, left parenthesis, right parenthesis, returns the Observable List of data items that make up this series. Row 2: Return value, void; Method name and argument list, set Name, left parenthesis, String, value, right parenthesis, sets the name to be displayed for this series.

Back to Table

Code for the controller in the Bar Chart application. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, asterisk, Bar Chart View Controller class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java f x, dot, event, dot, asterisk, semicolon. Line 6: import, java f x, dot, scene, dot, control, dot, asterisk, semicolon. Line 7: Blank. Line 8: public, class, Bar Chart View Controller, implements, Event Handler, left angle bracket, Action Event, right angle bracket. Line 9: Left brace. Line 10, indented once: private, Bar Chart View, view, semicolon. Line 11, indented once: private, Investment, left square brace, right square brace, investments, semicolon. Line 12: Blank. Line 13, indented once: public, Bar Chart View Controller, left parenthesis, Bar Chart View, view, comma. Line 14, indented a few times: Investment, left square brace, right square brace, investments, right parenthesis. Line 15, indented once: Left brace. Line 16, indented twice: this, dot, investments, equals, investments, semicolon. Line 17, indented twice: this, dot, view, equals, view, semicolon. Line 18, indented twice: left parenthesis, this, dot, view, right parenthesis, dot, set Button Listener, left parenthesis, this, right parenthesis, semicolon. Line 19, indented once: right brace. Line 20: Blank. Line 21, indented once: public, void, handle, left parenthesis, Action Event, event, right parenthesis. Line 22, indented once: left brace. Line 23, indented twice: forward slash, forward slash, update the model. Line 24, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, investments, dot, length, semicolon, i, plus, plus, right parenthesis. Line 25, indented 3 times: investments, left square brace, i, right square, brace, dot, update, left parenthesis, right parenthesis, semicolon. Line 26, indented twice: forward slash, forward slash, update the view. Line 27, indented twice: view, dot, update, left parenthesis, investments, right parenthesis, semicolon. Line 28, indented once: right brace. Line 29: right brace.

Back to Example

Code in the Investment Application dot java file. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, asterisk, Investment Application class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java f x, dot, application, dot, Application, semicolon. Line 6: import, java f x, dot, scene, dot, Scene, semicolon. Line 7: import, java f x, dot, stage, dot, Stage, semicolon. Line 8: Blank. Line 9: public, class, Investment Application, extends, Application. Line 10: Left brace. Line 11, indented once: at, Override. Line 12, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis. Line 13, indented once: Left brace. Line 14, indented twice: i n t, years, equals, 4, semicolon. Line 15, indented twice: Stocks, stocks, equals, new, Stocks, left parenthesis, years, right parenthesis, semicolon. Line 16, indented twice: Bonds, bonds, equals, new, Bonds, left parenthesis, years, right parenthesis, semicolon. Line 17, indented twice: Investment, left square brace, right square brace, equals, left brace, bonds, comma, stocks, right brace, semicolon. Line 18: Blank. Line 19, indented twice: Bar Chart View, root, equals, new, Bar Chart View, left parenthesis, 2020, comma, investments, right parenthesis, semicolon. Line 20: Blank. Line 21, indented twice: Scene, scene, equals, new, Scene, left parenthesis, root, comma, 540, comma, 510, right parenthesis, semicolon. Line 22, indented twice: stage, dot, set Title, left parenthesis, open quotes, Financial Projections, close quotes, right parenthesis, semicolon. Line 23, indented twice: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Line 24, indented twice: stage, dot, show, left parenthesis, right parenthesis, semicolon. Line 25: Blank. Line 26, indented twice: Bar Chart View Controller, controller. Line 27, indented 3 times: equals, new, Bar Chart View Controller, left parenthesis, root, comma, investments, right parenthesis, semicolon. Line 28, indented twice: right brace. Line 29: Blank. Line 30, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 31, indented once: left brace. Line 32, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 33, indented once: right brace. Line 34: right brace.

Back to Example

Code in the Java F X style sheet for the Simple Math application. Program code. In the code, the words in the variable names are merged. Line 1: V Box. Line 2: Left brace. Line 3, indented once: hyphen, f x hyphen background hyphen color, colon, sky blue, semicolon. Line 4: right brace. Line 5: blank. Line 6: Label. Line 7:

Left brace. Line 8, indented once: hyphen f x hyphen background hyphen color: deep sky blue, semicolon. Line 9, indented once: hyphen f x hyphen text hyphen fill, colon, blue, semicolon. Line 10: right brace. Line 11: Blank. Line 12: hash, result. Line 13: Left brace. Line 14, indented once: hyphen f x hyphen background hyphen color, colon, aqua, semicolon. Line 15, indented once: hyphen f x hyphen font hyphen weight, colon, bold, semicolon. Line 16: right brace. Line 17: Blank. Line 18: Button, colon, hover. Line 19: Left brace. Line 20, indented once: hyphen f x hyphen background hyphen color, colon, hash 0 0 F F 0 0, semicolon. Line 21: right brace.

Back to Example

Code in which a style sheet has been imported. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Simple Math Operations Using Buttons. Line 2: Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: Blank. Line 5: import, java, dot, net, dot, U R L, semicolon. Line 6: import, java f x, dot, application, dot, Application, semicolon. Line 7: import, java f x, dot, f x m l, dot, F X M L Loader, semicolon. Line 8: import, java f x, dot, scene, dot, layout, dot, V Box, semicolon. Line 9: import, java f x, dot, scene, dot, Scene, semicolon. Line 10: import, java f x, dot, stage, dot, Stage, semicolon. Line 11: Blank. Line 12: public, class, Simple Math Practice, extends, Application. Line 13: Left brace. Line 14, indented once:

at, Override. Line 15, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis, forward slash, forward slash, throws Exception. Line 16, indented once: Left brace. Line 17, indented twice: try. Line 18, indented twice: Left brace. Line 19, indented 3 times: U R L, u r l, equals. Line 20, indented 4 times: get Class, left parenthesis, right parenthesis, dot, get Resource, left parenthesis, open quotes, f x m l underscore simple underscore math, dot, f x m l, close quotes, right parenthesis, semicolon. Line 21, indented 3 times: V Box, root, equals, F X M L Loader, dot, load, left parenthesis, u r l, right parenthesis, semicolon. Line 22, indented 3 times: Scene, scene, equals, new, Scene, left parenthesis, root, comma, 300, comma, 275, right parenthesis, semicolon. Line 23, indented 3 times: scene, dot, get Style sheets, left parenthesis, right parenthesis, dot, add, left parenthesis, open quotes, simple underscore math, dot, c s s, close quotes, right parenthesis, semicolon. Line 24, indented 3 times: stage, dot, set Title, left parenthesis, open quotes, Simple Math, close quotes, right parenthesis, semicolon. Line 25, indented 3 times: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Line 26, indented 3 times: stage, dot, show, left parenthesis, right parenthesis, semicolon. Line 27, indented twice: right brace. Line 28, indented twice: catch, left parenthesis, Exception, e, right parenthesis. Line 29, indented twice: left brace. Line 30, indented 3 times: e, dot, print Stack Trace, left parenthesis, right parenthesis, semicolon. Line 31, indented twice: right brace. Line 32, indented once: right brace. Line 33: Blank. Line 34, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 35, indented once: left brace. Line 36, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 37, indented once: right brace. Line 38: right brace.

Back to Example

A table detailing the Game View class A P I. Constructor: Game View, left parenthesis, i n t, n Sides, right parenthesis, instantiates a tile puzzle View having an n Sides-by-n Sides grid. Return value: void. Method name and argument list: set Up Game, left parenthesis, i n t, n Sides, right parenthesis, resets the grid as an n Sides-by-n Sides grid.

Back to Table

A table detailing operator precedence. The table has 11 rows and 3 columns. It has the following column headings. Operators. Order of Same-Statement Evaluation. Operation. The row details in the table are the following. Row 1: Operators, Left parenthesis, right parenthesis; Order of Same-Statement Evaluation, left to right; Operation, parentheses for explicit grouping. Row 2: Operators, plus plus, minus minus; Order of Same-Statement Evaluation, right to left; Operation, shortcut post increment and post decrement. Row 3: Operators, plus plus, minus minus, not; Order of Same-Statement Evaluation, right to left; Operation, shortcut preincrement and predecrement, logical unary NOT. Row 4: Operators, asterisk, forward slash, percentage; Order of Same-Statement Evaluation, left or right; Operation, multiplication, division, modulus. Row 5: Operators, plus, minus; Order of Same-Statement Evaluation, left to right; Operation, addition or String concatenation, subtraction. Row 6: Operators, less than, less than or equals, greater than, greater than or equals, instance of; Order of Same-Statement Evaluation, left to right; Operation, relational operators: less than, less than or equal to, greater than, greater than or equal to; instance of. Row 7: Operators, equals equals, not equals; Order of Same-Statement Evaluation, left or right; Operation, equality operators: equal to and not equal to. Row 8: Operators, and and; Order of Same-Statement Evaluation, left tor right; Operation, logical AND. Row 9: Operators, or or; Order of Same-Statement Evaluation, left to right; Operation, logical OR. Row 10: Operators, question mark colon; Order of Same-Statement Evaluation, left to right; Operation, conditional operator. Row 11: Operators, equals, plus equal, minus equals, asterisk equals, forward slash, equals, percentage equals; Order of Same-Statement Evaluation, right to left; Operation, assignment operator and shortcut assignment operators.

Back to Table

The calculation by which the binary number a is converted to its decimal equivalent. a is a positive integer and has the value 0 0 0 0 0 1 0 1 0 1 1 1 1 0 0 1. The value of a is calculated as given below. a equals 2 to the power of 10 plus 2 to the power of 8 plus 2 to the power of 6 plus 2 to the power of 5 plus 2 to the power of 4 plus 2 to the power of 3 plus 2 to the power of 0. This equals 1024 plus 256 plus 64 plus 32 plus 16 plus 8 plus 1. This equals 1401.

Back to Code

The formula to calculate the two's complement of a number. Two's complement of n equals 2 d minus n.

Back to Code

Simplification of the formula to calculate the two's complement of a number. Two's complement of n equals 2 to the power of d minus 1 minus n plus 1.

Back to Code

The calculation for finding out two's complement of b. b is a negative integer that has the value 1 1 1 1 1 1 1 1 1 0 1 1 0 1 0. 2 to the power of d minus 1 is 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1. b is 1 1 1 1 1 1 1 1 1 0 1 1 0 1 0. 2 to the power of d minus 1 minus b is 0 0 0 0 0 0 0 0 0 1 0 0 1 0 1. 2 to the power of d minus 1 minus b plus 1 gives the two's complement of b which is 0 0 0 0 0 0 0 0 0 1 0 0 1 1 0.

Back to Code

Two's complement of b calculated by inverting each bit and adding 1. b is a negative integer that has the value 1 1 1 1 1 1 1 1 1 1 0 1 1 0 1 0. b inverted is 0 0 0 0 0 0 0 0 0 1 0 0 1 0 1. b inverted plus 1 gives c which is 0 0 0 0 0 0 0 0 0 0 1 0 0 1 1 0.

Back to Code

Verification that the two's complement of b is correct by calculating the sum of b and c. b is 1 1 1 1 1 1 1 1 1 1 0 1 1 0 1 0. c is 0 0 0 0 0 0 0 0 0 0 1 0 0 1 1 0. b plus c is 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0.

Back to Code

C is converted to decimal which gives the original number, b. b equals minus of 2 to the power of 5 plus 2 to the power of 2 plus 2 to the power of 1. This equals minus of 32 plus 4 plus 2. This equals minus 38.

Back to Code

The largest positive number that can be represented. 0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1. max equals 2 to power of 14 plus 2 to the power of 13 plus 2 to the power of 12 plus 2 to the power of 11 plus 2 to the power of 10 plus 2 to the power of 9 plus 2 to the power of 8 plus 2 to the power of 7 plus 2 to the power of 6 plus 2 to the power of 5 plus 2 to the power of 4 plus 2 to the power of 3 plus 2 to the power of 2 plus 2 to the power of 1 plus 2 to the power of 0.

Back to Code

The smallest negative number that can be represented using 16 bits. 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0.

Back to Code

Inverting the bits and adding 1. min is 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0. min inverted is 0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1. min inverted plus 1 gives two's complement which is 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0.

Back to Code

How single and double precision floating-point numbers are represented. In single-precision floating-point numbers, 1 bit represents the sign, 8 bits represent the biased exponent, and 23 bits represent the mantissa. In double-precision floating-point numbers, 1 bit represents the sign, 11 bits represent the biased exponent, and 52 bits represent the mantissa.

Back to Figure

The bias in floating point numbers is equal to 2 raised to the number of bits of the biased exponent minus 1 the whole minus 1.

Back to Figure

The bias for single precision is 2 raised to the power of 8 minus 1 the whole minus 1 which equals 2 to the power of 7 minus 1 which equals 127.

Back to Figure

How floating-point numbers are represented with real exponents from minus 127 to 128 with a bias of 127. Real exponents are from minus 127 to 0 and to 128. Bias of 127 is added to the real exponents. The biased exponents are 0 to 127 and to 255.

Back to Figure

The bias for double precision. 2 to the power of 11 minus 1 the whole minus 1 which equals 2 to the power of 10 minus 1 which is 1023.

Back to Figure

The form of a floating-point number. (minus 1) to the power of sign times (1 plus significand) times 2 to the power of biased exponent minus bias the whole.

Back to Figure

A single-precision I triple E 754 floating-point number. 0, 1 0 0 0 0 1 1 1, 1 1 0 1 0 0 0 0 and so on 0.

Back to Figure

The biased exponent 1 0 0 0 0 1 1 1 converted to decimal equals 2 to the power of 7 plus 2 to the power of 2 plus 2 to the power of 1 plus 2 to the power of 0. This equals 128 plus 4 plus 2 plus 1. This equals 135.

Back to Figure

Converting a single-precision I triple E 754 floating-point number to decimal. The number equals (minus 1) to the power of 0 times (1 plus .1101) times 2 to the power of 135 minus 127 the whole. This equals 1.1101 times 2 to the power of 8. This equals 1 1 1 0 1 0 0 0 0.

Back to Figure

Converting a single-precision I triple E 754 floating-point number to decimal. In decimal, the number is 2 to the power of 8 plus 2 to the power of 7 plus 2 to the power of 6 plus 2 to the power of 4. This equals 256 plus 128 plus 64 plus 16. This equals 464.

Back to Figure

Alternate method for converting a single-precision I triple E 754 floating-point number to decimal. The calculation equals 1.1101 times 2 to the power of 8. This equals (1 plus 1 times 1 divided by 2 of 1 plus 1 times 1 divided by 2 of 2 plus 0 times 1 divided by 2 of 3 plus 1 times 1 divided by 2 of 4) times 2 to the power of 8. This equals (1 plus 1 divided by 2 plus 1 divided by 4 plus 1 divided by 16) times 2 to the power of 8. This equals (1 plus 1 divided by 2 plus 1 divided by 4 plus 1 divided by 16) times 256. This equals 464.

Back to Figure

y represented in binary. y equals minus 101.11. This equals minus 1.01011 times 2 to the power of 2.

Back to Figure

Biased exponent equals 2 plus 127. This equals 129.

Back to Figure

Converting 129 to binary. 129 equals 1 0 0 0 0 0 0 1.

Back to Figure

The I triple E 754 single-precision value of the number y. 1, 1 0 0 0 0 0 0 1, 0 1 0 1 1 0 0 0 0 and so on to 0.

Back to Figure

The I triple E 754 single-precision value of the number y. 1, 1 0 0 0 0 0 0 1, 0 1 0 1 1 0 0 0 0 and so on to 0.

Back to Table

Line 1: set total to 0.00 dollars. Line 2: reach for first item. Line 3: if item is not the divider bar. Line 4, indented once: add price to total. Line 5: reach for next item. Line 6: if item is not the divider bar. Line 7, indented once: add price to total. Line 7: reach for next item. Line 8: if item is not the divider bar. Line 8, indented once: add price to total. Line 9: dot dot dot, left parentheses, finally, right parentheses. Line 10: reach for next item. Line 11: item is the divider bar, comma. Line 11, indented once: tell teh customer the total price.

Back to Code

Program code. The code contains the keyword while. Line 1: 2 forward slashes. initialize variables. Line 2: while, left parentheses, condition, right parentheses. Line 3: left brace. Line 4, indented once: 2 forward slashes. process data, semicolon, loop body. Line 5: right brace. Line 6: 2 forward slashes. process the results.

Back to Code

Line 1: set total to 0.00 dollars. Line 2: reach for first item. Line 3: while item is not the divider bar. Line 4: left brace. Line 5, indented once: add price to total. Line 6, indented once: reach for next item. Line 7: right brace. Line 8: 2 forward slashes. if we get here, comma, the item is the divider bar output the total price.

Back to Code

while, left parentheses, condition, right parentheses, semicolon. 2 forward slashes. semicolon causes endless loop if condition is true.

Back to Code

Line 1: initialize variables. Line 2: read the first data item.

2 forward slashes. priming read. Line 3: while data item is not the sentinel value. Line 4: left brace. Line 5, indented once: process the data. Line 6: blank. Line 7, indented once: read the next data item. 2 forward slashes. update read. Line 8: right brace. Line 9: report the results.

Back to Code

Line 1: initialize variables. Line 2: while data item is not the sentinel value. Line 3: left brace. Line 4, indented once: read the next data. Line 5, indented once: process the data. Line 6: right brace. Line 7: report the results.

Back to Code

Line 1: initialize variables. Line 2: while we have not reached end of file. Line 3: left brace. Line 4, indented once: read the next data item. Line 5, indented once: process the data. Line 6: right brace. Line 7: report the results.

Back to Code

Line 1: set total to 0. Line 2: read a number, 2 forward slashes, priming read. Line 3: while the number is not the sentinel value. Line 4: left brace. Line 5, indented once: add the number to total. Line 6, indented once: read the next number, 2 forward slashes, update read. Line 7: right brace. Line 8: output the total.

Back to Code

Line 1: set count Passed to 0. Line 2: read a test score. Line 3: while the test score is not the sentinel value. Line 4: left brace. Line 5, indented once: if the test score, right angled bracket, equals sign, 60.

Back to Code

Line 1: set total to 0. Line 2: set count to 0. Line 3: read a number. Line 4: while the number is not the sentinel value. Line 5: left brace. Line 6, indented once: add the number to total. Line 7, indented once: add 1 to the count. Line 8: blank. Line 9, indented once: read the next number. Line 10: right brace. Line 11: right brace. Line 12: set the average to total, forward slash, count. Line 13: output the average.

Back to Code

double average equals left parentheses, double, right parentheses, total, forward slash, count, semicolon.

Back to Code

Line 1: read a first number and make it the maximum. Line 2: while there is another number to read. Line 3: left brace. Line 4, indented once: read the next number. Line 5, indented once: if number greater than maximum. Line 6, indented once: left brace. Line 7, indented twice: set maximum to number. Line 8, indented once: right brace. Line 8: right brace. Line 9: output the maximum.

Back to Code

while, left parentheses, option exclamation mark, equals sign, single quote, uppercase s, single quote, 2 pipes, option, exclamation mark, equals sign, single quote, lowercase s, single quote, right parentheses, 2 forward slashes, INCORRECT.

Back to Code

left parentheses, option, 2 equals sign, single quote, uppercase s, single quote, 2 pipes, option, 2 equals sign, single quote, lowercase s, single quote, right parentheses.

Back to Code

exclamation mark, left parentheses, option, 2 equals sign, single quote, uppercase s, single quote, 2 pipes, option, 2 equals sign, single quote, lowercase s, single quote, right parentheses.

Back to Code

left parentheses, option, exclamation mark, equals sign, single quote, uppercase s, single quote, 2 ampersands, option, exclamation mark, single quote, lowercase s, single quote, right parentheses.

Back to Code

Line 1: 2 forward slashes. initialize variables. Line 2: do. Line 3: left brace. Line 4, indented once: 2 forward slashes. body of loop. Line 5: right brace, while, left parentheses, condition, right parentheses, semicolon. Line 6: 2 forward slashes. process the results.

Back to Code

Program code. The code contains the keyword if. Line 1: System dot out dot print, left parentheses, double quotes, Enter a number between 1 and 10, right angled bracket, double quotes, right parentheses, semicolon. Line 2: number equals scan dot next Int, left parentheses, right parentheses, semicolon. Line 3: if, left parentheses, number less than 1, 2 pipes, number greater than 10, right parentheses, 2 forward slashes, INCORRECT, exclamation mark. Line 4: left brace. Line 5, indented once: System dot out dot print, left parentheses, double quotes, Enter a number between 1 and 10, right angled bracket, double quotes, right parentheses, semicolon. Line 6, indented once: number equals scan dot next Int, left parentheses, right parentheses, semicolon. Line 7: right brace.

Back to Code

Program code. The code contains the keywords: int, for. Line 1: int sum equals 0, semicolon. Line 2: for, left parentheses, int i equals 10, semicolon, i greater than 5, semicolon, i minus, minus, right parentheses. Line 3: left brace. Line 4, indented once: sum, plus, equals, i, semicolon. Line 5: right brace.

Back to Code

Program code. The code contains the following keywords: for, int. Line 1: for, left parentheses, int i equals 0, semicolon, i less than 5, semicolon, i plus, plus, right parentheses. Line 2: left brace. Line 3, indented once: System dot out dot print l n, left parentheses, Math dot max, left parentheses, i, comma, 3, right parentheses, right parentheses, semicolon. Line 4: right brace.

Back to Code

Program code. The code contains the following keywords: int, while. Line 1: int i equals 0, semicolon. Line 2: int sum equals 0, semicolon. Line 3: while, left parentheses, i, exclamation mark, equals sign, 7, right parentheses. Line 4: left brace. Line 5, indented once: sum, plus, equals, i, semicolon. Line 6, indented once: i plus, plus, semicolon. Line 7: right brace.

Back to Code

Line 1: Random random equals new Random, left parentheses, right parentheses, semicolon. Line 2: int i equals random dot next Int, left parentheses, 5, right parentheses, plus, 3, semicolon.

Back to Code

Line 1: System dot out dot print, left parentheses, double quotes, Enter a starting integer, right angled bracket, double quotes, right parentheses, semicolon. Line 2: int start, equals, scan dot next Int, left parentheses, semicolon. Line 3: 2 forward slashes, your code goes here.

Back to Code

Line 1: System dot out dot print, left parentheses, double quotes, Enter an integer value, comma, double quotes. Line 2, indented multiple times: plus, double quotes, enter negative 1 to stop, right angled bracket, double quotes, right parentheses, semicolon. Line 3: int value equals scan dot next Int, left parentheses, right parentheses, semicolon. Line 4: 2 forward slashes, your code goes here.

Back to Code

Line 1: int sum equals 0, semicolon. Line 2: int count Multiples Of 7 equals 0, semicolon. Line 3: int count equals 1, semicolon. Line 4:2 forward slashes, your code goes here.

Back to Code

Program code. The code contains the following keywords: String, while. Line 1: String sentence equals, double quotes, double quotes, semicolon. Line 2: String word, semicolon. Line 3: 2 forward slashes, your code goes here. Line 4: blank. Line 5: while, left parentheses, exclamation mark, word dot equals, left parentheses, double quotes, end, double quotes, right parentheses, right parentheses. Line 6: left brace. Line 7, indented once: 2 forward slashes, and your code goes here. Line 8: blank. Line 9: right brace. Line 10: System dot out dot print l n, left parentheses, double quotes, The sentence is, double quotes, plus, sentence, right parentheses, semicolon.

Back to Code

Line 1: int sum equals 0, semicolon. Line 2: 2 forward slashes, your code goes here.

Back to Code

Program code. The code contains the following keywords:

int, while. Line 1: int i equals 0, semicolon. Line 2: while, left parentheses, i less than 5, right parentheses. Line 3: left brace. Line 4, indented once: System dot out dot print l n, left parentheses, double quotes, Hi there, double quotes, right parentheses, semicolon. Line 5, indented once: i plus, plus. Line 6: right brace. Line 7: blank. Line 8: 2 forward slashes, your code goes here.

Back to Code

Line 1: int sum equals 0, semicolon. Line 2: 2 forward slashes, your code goes here.

Back to Code

Program code. The code contains the keywords: int, while. Line 1: int i equals 0, semicolon. Line 2: while, left parentheses, i less than 3, right parentheses. Line 3, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: int, while. Line 1: int num, semicolon. Line 2: Scanner scan equals new Scanner, left parentheses, System dot in, right parentheses, semicolon. Line 3: while, left parentheses, num, exclamation mark, equals sign, negative 1, right parentheses. Line 4: left brace. Line 5, indented once: System dot out dot print, left parentheses, double quotes, Enter an integer, right angled bracket, double quotes, right parentheses, semicolon. Line 6, indented once: num equals scan dot next Int, left parentheses, right parentheses, semicolon. Line 2, indented once: System dot out dot print l n, left parentheses, num, right parentheses, semicolon. Line 3: right brace.

Back to Code

Program code. The code contains the keyword for. Line 1: for, left parentheses, int i equals 0, semicolon, i less than 3, semicolon, i plus, plus, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the keyword for. Line 1: for, left parentheses, int i equals 10, semicolon, i greater than 0, semicolon, i plus, plus, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: int, while. Line 1: Random random equals new Random, left parentheses, right parentheses, semicolon. Line 2: int number equals 1 plus random dot next Int, left parentheses, 10, right parentheses, semicolon. Line 3: while, left parentheses, number, exclamation mark, equals, 5, 2 pipes, number, exclamation mark, equals, 7, right parentheses. Line 4: left brace. Line 5, indented once: number equals 1 plus random dot next Int, left parentheses, 10, right parentheses, semicolon. Line 6: right brace. Line 7: System dot out dot print l n, left parentheses, double quotes, The number is, double quotes, plus, number, right parentheses, semicolon.

Back to Code

Program code. The code contains the keywords: int, for. Line 1: int sum equals 0, semicolon. Line 2: for, left parentheses, int i equals 1, semicolon, i less than 6, semicolon, i plus, plus, right parentheses. Line 3, indented once: sum plus, equals, i, semicolon. Line 4: blank. Line 5: System dot out dot print l n, left parentheses, double quotes, The value of i is, double quotes, plus i, right parentheses, semicolon.

Back to Code

Program code. The code contains the keywords int, dot, while. Line 1: int i equals 0, semicolon. Line 2: int sum equals 0, semicolon. Line 3: do. Line 4: left brace. Line 5, indented once: sum plus equals i, semicolon. Line 6, indented once: i plus, plus, semicolon. Line 7: right brace, while, left parentheses, i less than 3, right parentheses, 2 forward slashes, line 11.

Back to Code

Line 1: Test dot java, colon, 11, colon, error, colon, single quote, semicolon, single quote, expected. Line 2: while, left parentheses, i less than 3, right parentheses, 2 forward slashes, line 11. Line 3: a caret sign below the first forward slash in Line 2. Line 4: 1 error.

Back to Code

Program code. The code contains the keywords: int, while. Line 1: int i equals 0, semicolon. Line 2: while, left parentheses, i less than 3, right parentheses. Line 3: left brace. Line 4, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 5, indented once: i minus, minus, semicolon. Line 6: right brace.

Back to Code

Program code. The code contains the keywords: for, int. Line 1: for, left parentheses, int i equals 0, semicolon, i plus, plus, semicolon, i less than 3, right parentheses, 2 forward slashes, line 5. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.

Back to Code

Line 1: Test dot java, colon, 5, colon, error, colon, not a statement. Line 2: for, left parentheses, int i equals 0, semicolon, i plus, plus, semicolon, i less than 3, right parentheses, 2 forward slashes, line 5. Line 3: a caret sign under the less than sign in Line 2. Line 4: 1 error.

Back to Code

Program code. The code contains the keywords: for, int. Line 1: for, left parentheses, int i equals 1, semicolon, i less than 3, semicolon, i plus plus, right parentheses, 2 forward slashes, line 5. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the keywords: int, for. Line 1: int product equals 1, semicolon. Line 2: for, left parentheses, int i equals 1, comma, i less than 5, comma, i plus, plus, right parentheses, 2 forward slashes, line 8. Line 3, indented once: product, asterisk, equals, i, semicolon. Line 4: System dot out dot print l n, left parentheses, double quotes, Product is, double quotes, plus, product, right parentheses, semicolon. 2 forward slashes, line 10.

Back to Code

Line 1: Test dot java, colon, 8, colon, error, colon, single quote, semicolon, single quote, expected. Line 2, indented once: for, left parentheses, int i equals 1, comma, i less than 5, comma, i plus, plus, right parentheses, 2 forward slashes, line 8. Line 3: a caret sign below the less than symbol in Line 2. Line 4: Test dot java, colon, 8, colon, error, colon, illegal start of type. Line 5, indented once: for, left parentheses, int i equals 1, comma, i less than 5, comma, i plus, plus, right parentheses, 2 forward slashes, line 8. Line 6: a caret sign under 5 in Line 5. Line 7: 2 errors.

Back to Code

Program code. The code contains the following keywords: for, int. Line 1: for, left parentheses, int i equals 0, semicolon, i less than 3, semicolon, i plus, plus, right parentheses. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon. Line 3: System dot out dot print l n, left parentheses, double quotes, i equals, double quotes, plus, i, right parentheses, semicolon, 2 forward slashes, line 8.

Back to Code

Line 1: Test dot java, colon, 8, colon, error, colon, cannot find symbol. Line 2, indented once: System dot out dot print l n, left parentheses, double quotes, i equals, double quotes, plus, i, right parentheses, semicolon, 2 forward slashes, line 8. Line 3: a caret sign under the second lowercase i in Line 2. Line 4: symbol, colon, variable i. Line 5: location, colon, class Test. Line 6: 1 error.

Back to Code

Program code. The code contains the following keywords: int, for. Line 1: int i equals 0, semicolon. Line 2: for, left parentheses, int i equals 0, semicolon, i less than 3, semicolon, i plus, plus, right parentheses, 2 forward slashes, line 6. Line 3, indented once: System dot out dot print l n, left parentheses, double quotes, Hello, double quotes, right parentheses, semicolon.

Back to Code

Line 1: Test dot java, colon, 6, colon, error, colon, variable i is already defined in method main, left parentheses, string, left square bracket, right square bracket, right parentheses. Line 2: for, left parentheses, int i equals 0, semicolon, i less than 3, semicolon, i plus, plus, right parentheses, 2 forward slashes, line 6. Line 3: a caret sign under the first lowercase i in Line 2. Line 3: 1 error.

Back to Code

The syntax is as follows. Line 1: access Modifier class Class Name. Line 2: left brace. Line 3, indented once: 2 forward slashes, class definition goes here. Line 4: right brace.

Back to Code

Line 1: public class Auto. Line 2: left brace. Line 3: right brace.

Back to Code

The syntax is as follows. access Modifier data Type identifier List, semicolon.

Back to Code

Line 1: private String name equals, double quotes, double quotes, semicolon, 2 forward slashes, an empty string. Line 2: private final int PERFECT underscore SCORE equals 100, comma, PASSING underscore SCORE equals 60, semicolon. Line 3: private int start X, comma, start Y, comma, width, comma, height, semicolon.

Back to Code

Program code. The code contains the keywords public, class, private, String, int, and double. Line 1: public class Auto. Line 2: left brace. Line 3, indented once: private String model, semicolon. Line 4, indented once: private int miles Driven, semicolon. Line 5, indented once: private double gallons Of Gas, semicolon. Line 6: right brace.

Back to Code

The syntax is as follows. Line 1: access Modifier return Type method Name, left parentheses, parameter list, right parentheses, 2 forward slashes, method header. Line 2: left brace. Line 3, indented once: 2 forward slashes, method body. Line 4: right brace.

Back to Code

The syntax is as follows. illegal start of expression.

Back to Code

The syntax is as follows. single quote, semicolon, single quote, expected.

Back to Code

Program code. The code contains the keywords public, static, void, and String. Line 1: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, application code. Line 4: right brace.

Back to Code

The syntax is as follows. return expression, semicolon.

Back to Code

The syntax is as follows. return, semicolon.

Back to Code

The syntax is as follows. Line 1: access Modifier Class Name, left parentheses, parameter list, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, constructor body. Line 4: right brace.

Back to Code

Program code. The code contains the keywords public, void, String, int, double. Line 1: 2 forward slashes, Error, exclamation mark, void return value specified. Line 2: public void Auto, left parentheses, String model, comma. Line 3, indented multiple times: int start Miles Driven, comma. Line 4, indented multiple times: double start Gallons Of Gas, right parentheses. Line 5: left brace. Line 6, indented once: 2 forward slashes, body of constructor. Line 7: right brace.

Back to Code

Auto g m, equals, new Auto, left parentheses, double quotes, Prius, double quotes, comma, 350, comma, 15.5, right parentheses, semicolon.

Back to Code

Line 1: Auto Client, dot, java, colon, 13, colon, error, colon, constructor Auto in class Auto cannot be applied to given types, semicolon. Line 2, indented once: Auto g m, equals, new Auto, left parentheses, double quotes, Prius, double quotes, comma, 350, comma, 15.5, right parentheses, semicolon. Line 3: a caret sign under n of new in Line 2. Line 4, indented once: required, colon, no arguments. Line 5, indented once: found, colon, String, comma, int, comma, double. Line 6, indented once: reason, colon, actual and formal argument lists differ in length. Line 7: 1 error.

Back to Code

cannot find symbol.

Back to Code

Program code. The code contains the keywords public and void. Line 1: pubilc void set Instance Variable, left parentheses, data Type new Value, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, validate new Value, comma, then assign to the instance variable. Line 4: right brace.

Back to Code

Program code. The code contains the keywords public, void and String. Line 1: 2 forward slashes, Incorrect, exclamation mark, parameter hides instance variable. Line 2: public void set Model, left parentheses, String model, right parentheses. Line 3: left brace. Line 4, indented once: model equals model, semicolon. Line 5: right brace.

Back to Code

Program code. The code contains the keywords public, void, and String. Line 1: 2 forward slashes, Incorrect, exclamation mark, declared local variable hides instance variable. Line 2: public void set Model, left parentheses, String new Model, right parentheses. Line 3: left brace. Line 4, indented once: String model, semicolon, 2 forward slashes, declared variable hides instance variable. Line 5, indented once: model equals new Model, semicolon. Line

6: right brace.

Back to Code

Program code. The code contains the keywords public, void, and String. Line 1: 2 forward slashes, Incorrect, exclamation mark, Declaring the parameter, semicolon, parameters are declared already. Line 2: public void set Model, left parentheses, String new Model, right parentheses. Line 3: left brace. Line 4, indented once: String new Model, semicolon. 2 forward slashes, local variable has same name as parameter. Line 5, indented once: model equals new Model, semicolon. Line 6: right brace.

Back to Code

variable new Model is already defined in method set Model, left parentheses, String, right parentheses.

Back to Code

Program code. The code contains the keywords public, void, String, and this. Line 1: public void set Model, left parentheses, String model, right parentheses. Line 2: left brace. Line 3, indented once: this dot model equals model, semicolon. Line 4: right brace.

Back to Code

Program code. The code contains the keywords public, String, this, and return. Line 1: public Auto set Model, left parentheses, String model, right parentheses. Line 2: left brace. Line 3, indented once: this dot model equals model, semicolon. Line 4, indented once: return this, semicolon. Line 5: right brace.

Back to Code

sporty dot set Gallons Of Gas, left parentheses, 3.4, right parentheses, dot, set Miles Driven, left parentheses, 67, right parentheses, semicolon.

Back to Code

Left parentheses, sporty dot set Gallons Of Gas, left parentheses, 3.4, right parentheses, right parentheses, dot set Miles Driven, 67, right parentheses, semicolon.

Back to Code

Left parentheses, sporty, right parentheses, dot, set Miles Driven, left parentheses, 67, right parentheses, semicolon.

Back to Code

Line 1: public String to String, left parentheses, right parentheses. Line 2: public boolean equals, left parentheses, Object o, right parentheses.

Back to Code

Program code. The code contains the keyword if. Line 1:

if, left parentheses, o, instance Of, Auto, right parentheses. Line 2: left brace. Line 3, indented once: Auto o b j Auto equals, left parentheses, Auto, right parentheses, o, semicolon. Line 3, indented once: 2 forward slashes, call methods of the Auto class with o b j Auto.

Back to Code

The error reads: non, hyphen, static variable x x x cannot be referenced from a static context.

Back to Code

a forward slash b, plus, c forward slash d, equals, left parentheses, a asterisk d, right parentheses, forward slash, left parentheses, b asterisk d, right parentheses, plus, left parentheses, b asterisk c, right parentheses, forward slash, left parentheses, b asterisk d, right parentheses, equals, left parentheses, a asterisk d, plus, b asterisk c, right parentheses, forward slash, left parentheses, b asterisk d, right parentheses.

Back to Code

left parentheses, a, forward slash, b, right parentheses, asterisk, left parentheses, c, forward slash, d, right parentheses, equals, left parentheses, a asterisk c, right parentheses, forward slash, left parentheses, b asterisk d, right parentheses.

Back to Code

Line 1: a equals g asterisk a 1. Line 2: b equals g asterisk b 1.

Back to Code

The steps are as follows. Step 1. 1635 equals 75 asterisk 21 plus 60, left parentheses, a equals 1635, comma, b equals 75, comma, q equals, 21, comma, r equals 60, right parentheses. Line 2: 75 equals 60 asterisk 1 plus 15, left parentheses, a equals 75, comma, b equals 60, comma, q equals 1, comma, r equals 15, right parentheses. Line 3: 60 equals 15 asterisk 4 plus 0, left parentheses a equals 60, comma, b equals 15, comma, q equals 4, comma, r equals 0, right parentheses.

Back to Code

The output reads: 10, forward slash, 5, in lowest terms is equal to 2.

Back to Code

Rational r 3, equals, r 1 dot add, left parentheses, r 2, right parentheses, semicolon. 2 forward slashes, r 1 and r 2 are two existing Rationals.

Back to Code

The output reads: 3, forward slash, 5, plus, 2, forward slash, 3, equals, 19, forward slash, 15.

Back to Code

The syntax is as follows. enum Enum Name, left brace, o b j 1, comma, o b j 2, comma, dot, dot, dot, right brace, semicolon, where o b j 1, o b j 2, et cetera, are names for the constant objects.

Back to Code

enum Days, left parentheses, SUN, comma, MON, comma, T U E, comma, WED, comma, T H U R, comma, FRI, comma, SAT, right brace, semicolon. The names of the constant objects are in uppercase.

Back to Code

The syntax is as follows: enum Type dot enum Object.

Back to Code

Days dot WED.

Back to Code

The error reads: an enum switch case label must be the unqualified name of an enumeration constant.

Back to Code

if, left parentheses, airport 1, 2 equals sign, airport 2, right parentheses.

Back to Code

Back to Table

The table has 2 rows labeled Value and Index. The

column entries are as follows. Column 1. Value: 5. Index: 0. Column 2. Value: 17 in bold font. Index: 1. Column 3. Value: 2 in bold font. Index: 2. Column 4. Value: 26. Index: 3. The columns from 1 to 3 are shaded and they are marked Unsorted subarray. Column 4 has the sorted element. An arrow pointing to Index 1 reads: j, left parentheses, inner loop counter, right parentheses.

Back to Table

The table has 2 rows labeled Value and Index. The column entries are as follows. Column 1. Value: 5 in bold font. Index: 0. Column 2. Value: 2 in bold font. Index: 1. Column 3. Value: 17. Index: 2. Column 4. Value: 26. Index: 3. The columns 1 and 2 are shaded and they are marked Unsorted subarray. Columns 3 and 4 are marked sorted elements. An arrow pointing to Index 0 reads: j, left parentheses, inner loop counter, right parentheses.

Back to Table

The table has 2 rows labeled Value and Index. The column entries are as follows. Column 1. Value: 2 in bold font. Index: 0. Column 2. Value: 5 in bold font. Index: 1. Column 3. Value: 17. Index: 2. Column 4. Value: 26. Index: 3. Column 1 is shaded. An arrow pointing to column 1 reads: Automatically sorted. Columns 2 to 4 are marked Sorted elements.

Back to Table

Line 1: read first survey. Line 2: while, left parentheses, not end of surveys, right parentheses.

Back to Code

Line 3: left brace. Line 4, indented once: if answer is 0. Line 5, indented twice: increment counter 0. Line 6, indented once: else if answer is 1. Line 7, indented twice: increment counter 1. Line 8, indented once: else if answer is 2. Line 9, indented twice: increment counter 2. Line 10, indented once: else if answer is 3. Line 11, indented twice: increment counter 3. Line 12, indented once: read next survey. Line 13: right brace.

Back to Code

roll Count, left square bracket, my Roll minus 1, right square bracket, plus, plus, semicolon.

Back to Code

The syntax is as follows. access Modifier return Type method Name, left parentheses, left parentheses, 0 to many parameters, comma, right parentheses, data Type, dot, dot, dot, last Parameter, right parentheses.

Back to Code

Line 1: double, left square bracket, right square bracket, a, equals, left brace, 12.5, comma, 48.3, comma, 65.0, right brace, semicolon. Line 2: System dot out dot print l n, left parentheses, a, left square bracket, 1, right square bracket, right parentheses, semicolon.

Back to Code

Line 1: int, left square bracket, right square bracket, a, equals, new int, left square bracket, 6, right square bracket, semicolon. Line 2: System dot out dot print l n, left parentheses, a, left square bracket, 4, right square bracket, right parentheses, semicolon.

Back to Code

Line 1: double, left square bracket, right square bracket, a, equals, left brace, 12.5, comma, 48.3, comma, 65.0, right brace, semicolon. Line 2: System dot out dot print l n, left parentheses, a dot length, right parentheses, semicolon.

Back to Code

Line 1: int, left square bracket, right square bracket, a, equals, left brace, 12, comma, 48, comma, 65, right brace, semicolon. Line 2: blank. Line 3: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, a, left square bracket, i, right square bracket, right parentheses, semicolon.

Back to Code

Line 1: int, left square bracket, right square bracket, a, equals, left brace, 12, comma, 48, comma, 65, right brace, semicolon. Line 2: blank. Line 4, indented once: System dot out dot print l n, left parentheses, double quotes, a, left square bracket, double quotes, i, plus, double quotes, right square bracket, equals, double quotes, plus, a, left square bracket, i, right square bracket, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: int, for. Line 1: int s equals 0, semicolon. Line 2: int, left square bracket, right square bracket, a, equals, left brace, 12, comma, 48, comma, 65, right brace, semicolon. Line 3: blank. Line 4: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 5, indented once: s plus equals a, left square bracket, i, right square bracket, semicolon. Line 6: System dot out dot print l n, left parentheses, double quotes, s equals, blank space, double quotes, plus s, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: int, new, for. Line 1: int, left square bracket, right square bracket, a, equals, new int, left square bracket, 18, right square bracket, semicolon. Line 2: blank. Line 3: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 4: a, left square bracket, i, right square bracket, equals, i plus 10, semicolon. Line 5: blank. Line 6: System dot out dot print l n, left parentheses, a, left square bracket, 4, right square bracket, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: double, for, int, if. Line 1: double, left square bracket, right square bracket, a, equals, left brace, 12.3, comma, 99.6, comma, 48.2, comma, 65.8, right brace, semicolon. Line 2: double temp equals a, left square bracket, 0, right square bracket, semicolon. Line 3: blank. Line 4: for, left parentheses, int, i equals 1, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 5: left brace. Line 6, indented once: if, left parentheses, a, left square bracket, i, right square bracket, greater than, temp, right parentheses. Line 7, indented twice: temp equals a, left parentheses, i, right parentheses, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: int, for. Line 1: int, left square bracket, right square bracket, a, equals, left brace, 12, comma, 48, comma, 65, comma, 23, right brace, semicolon. Line 2: int temp, equals, a, left square bracket, 1, right square bracket, semicolon. Line 3: a, left square bracket, 1, right square bracket, equals, a, left square bracket, 3, right square bracket, semicolon. Line 4: a, left square bracket, 3, right square bracket, equals, temp, semicolon.

Back to Code

Program code. The code contains the following keywords: public, int, for, if, return. Line 1: public int foo, left parentheses, int, left square bracket, right square bracket, a, right parentheses. Line 2: left brace. Line 3, indented once: int temp equals 0, semicolon. Line 4, indented once: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i plus, plus, right parentheses. Line 5, indented once: left brace. Line 6, indented twice: if, left parentheses, a, left square bracket, i, right square bracket, 2 equals sign, 5, right parentheses. Line 7, indented thrice: temp, plus, plus, semicolon. Line 8, indented once: right brace. Line 9, indented once: return temp, semicolon. Line 10: right brace.

Back to Code

Program code. The code contains the following keywords: public, int, for, if, return. Line 1: public int foo, left parentheses, int, left square bracket, right square bracket, a, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: if, left parentheses, a, left square bracket, i, right square bracket, 2 equals sign, 10, right parentheses. Line 6, indented thrice: return i, semicolon. Line 7, indented once: right brace. Line 8, indented once: return negative 1, semicolon. Line 9: right brace.

Back to Code

Program code. The code contains the following keywords: public, boolean, int, for, if, return, false, true. Line 1: public boolean foo, left parentheses, int, left square bracket, right square bracket, a, right parentheses. Line 2: left brace. Line 3, indented once: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: if, left parentheses, a, left square bracket, i, right square bracket, less than 0, right parentheses. Line 6, indented thrice: return false, semicolon. Line 7, indented once: right brace. Line 8, indented once: return true, semicolon. Line 9: right brace.

Back to Code

Program code. The code contains the following keywords: public, String, new, for, int, return. Line 1: public String, left square bracket, right square bracket, foo, left parentheses, String, left square bracket, right square bracket, a, right parentheses. Line 2: left brace. Line 3, indented once: String, left square bracket, right square bracket, temp, equals, new String, left square bracket, a dot length, right square bracket, semicolon. Line 4, indented once: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i plus, plus, right parentheses. Line 5, indented once: left brace. Line 6, indented twice: temp, left square bracket, i, right square bracket, equals, a, left square bracket, i, right square bracket, dot, to Lower Case, left parentheses, right parentheses, semicolon. Line 7, indented once: right brace. Line 8, indented once: return temp, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, boolean, String, new, for, int, if, else, true, false, return. Line 1: public boolean, left square bracket, right square bracket, foo, left parentheses, String, left square bracket, right square bracket, a, right parentheses. Line 2: left brace. Line 3, indented once: boolean, left square bracket, right square bracket, temp, equals, new boolean, left square bracket, a dot length, right square bracket, semicolon. Line 4, indented once: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i plus, plus, right parentheses. Line 5, indented once: left brace. Line 6, indented twice: if, left parentheses, a, left square bracket, i, right square bracket, dot index Of, left parentheses, double quotes, at symbol, double quotes, right parentheses, exclamation mark, equals, negative 1, right parentheses. Line 7, indented thrice: temp, left square bracket, i, right square bracket, equals, true, semicolon. Line 8, indented twice: else. Line 9, indented thrice: temp, left square bracket, i, right square bracket, equals, false, semicolon. Line 10, indented once: right brace. Line 11, indented once: return temp, semicolon. Line 12: right brace.

Back to Code

Program code. The code contains the following keywords: int, new, for. Line 1: int, left square bracket, right square bracket, a, equals, new int, left square bracket, 25, right square bracket, semicolon. Line 2: for, left parentheses, int i equals 0, semicolon, i less than a dot length, semicolon, i, plus, plus, right parentheses. Line 3: left brace. Line 4, indented once: 2 forward slashes, your code goes here. Line 5: right brace.

Back to Code

Program code. The code contains the following keywords: double, for, int. Line 1: double, left square bracket, right square bracket, a, equals, left brace, 45.2, comma, 13.1, comma, 12.8, comma, 87.4, comma, 99.0, comma, 100.1, comma, 43.8, comma, 2.4, right brace, semicolon. Line 3, indented once: System dot out dot print l n, left parentheses, a, left square bracket, i, right square bracket, right parentheses, semicolon, 2 forward slashes, line 28 of class Test dot java.

Back to Code

Line 1: 2. Line 2: 7. Line 3: 8. Line 4: 9. Line 5: 11. Line 6: 16. Line 7: Exception in thread, double quotes, main, double quotes, java dot lang dot Array Index Out Of Bounds. Line 8, indented once: Exception, colon, Index 6 out of bounds for length 6. Line 9: at Test dot main, left parentheses, Test 46 dot java, colon, 28, right parentheses.

Back to Code

Program code. The code contains the following keywords: int, if, else. Line 1: int, left square bracket, right square bracket, a, equals, left brace, 1, comma, 2, comma, 3, right brace, semicolon. Line 2: int, left square bracket, right square bracket, b, equals, left brace, 1, comma, 2, comma, 3, right brace, semicolon. Line 3: if, left parentheses, a, 2 equals sign, b, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, double quotes, Arrays are equal, double quotes, right parentheses, semicolon. Line 5: else. Line 6, indented once: System dot out dot print l n, left parentheses, double quotes, Arrays are NOT equal, double quotes, right parentheses, semicolon.

Back to Code

Line 1: int, left square bracket, right square bracket, a, equals, left brace, 1, comma, 2, comma, 3, right brace, semicolon. Line 2: System dot out dot print l n, left parentheses, a, right parentheses, semicolon.

Back to Code

The output is as follows. left square bracket, uppercase I, at symbol, lowercase f, 0, 3, 2, 6, 2, 6, 7.

Back to Code

The syntax is as follows: Line 1: access Modifier class Subclass Name extends Superclass Name. Line 2: left brace. Line 3, indented once: 2 forward slashes, class definition. Line 4: right brace.

Back to Code

public class Draw A Sprite extends Application.

Back to Code

super, left parentheses, argument list, right parentheses, semicolon.

Back to Code

call to super must be first statement in constructor.

Back to Code

this dot balance equals balance, semicolon.

Back to Code

balance has private access in Bank Account.

Back to Code

The syntax is as follows: super dot method Name, left parentheses, argument list, right parentheses.

Back to Code

The syntax is as follows: access Method abstract class Class Name.

Back to Code

The syntax is as follows: access Modifier abstract return Type method Name, left parentheses, argument list, right parentheses, semicolon.

Back to Code

The error reads: class Name is abstract, semicolon, cannot be instantiated.

Back to Code

Line 1: Forward slash, 2 asterisks, prepare To Race method. Line 2: Asterisk, at symbol param input racer type entered by the user. Line 3: Asterisk, racer types are, single quote, t, single quote, or, single quote, T, single quote, for Tortoise. Line 4: Asterisk, single quote, h, single quote, or , single quote, H, single quote, for Hare. Line 5: Asterisk, Forward slash. Line 6: private void prepare To Race, left parentheses, char input, right parentheses. Line 7: Left brace. Line 8: final int START underscore LINE equals 60, semicolon. 2 forward slashes, x position of start of race. Line 9: final int RACER underscore SPACE equals 50, semicolon. 2 forward slashes, spacing between racers. Line 10: Forward slash, 2 asterisks, 1. Asterisk, Asterisk, Asterisk, Asterisk, Asterisk, Student writes this switch statement. Line 11: Asterisk, input parameter contains the racer type. Line 12: Asterisk, entered by the user. Line 13: Asterisk, If input is, single quote, T, single quote, or, single quote, t, single quote. Line 14: Asterisk, add a Tortoise object to the Array List named racer List. Line 15: Asterisk, which is an instance variable of this class. Line 16: Asterisk, The A P I of the Tortoise constructor is, colon. Line 17: Asterisk, Tortoise, left parentheses, String I D, int x, int y , right parentheses. Line 18: Asterisk, a sample call to the constructor is. Line 19: Asterisk, new Tortoise, left parentheses, double quotes, Tortoise, double quotes, START underscore LINE, y Pos , right parentheses. Line 20: Asterisk, where START underscore LINE is a constant local variable. Line 21: Asterisk, representing the starting x position for the race. Line 22: Asterisk, and y Pos is an instance variable representing. Line 23: Asterisk, the racer, single quote, s y position. Line 24: Asterisk. Line 25: Asterisk, If input is, single quote, H, single quote, or, single quote, h, single quote. Line 26: Asterisk, add a Hare object to the Array List named racer List. Line 27: Asterisk, The A P I of the Hare constructor is, colon. Line 28: Asterisk, Hare, left parentheses, String I D, int x, int y , right parentheses. Line 29: Asterisk, a sample call to the constructor is. Line 30: Asterisk, new Hare, left parentheses, double quotes, Hare, double quotes, START underscore LINE, y P o s, right parentheses. Line 31: Asterisk, where START underscore LINE is a constant local variable. Line 32: Asterisk, representing the starting x position for the race. Line 33: Asterisk, and y Pos is an instance variable representing. Line 34: Asterisk, the racer, single quote, s y position. Line 35: Asterisk. Line 36: Asterisk, After adding a racer to the Array List racer List. Line 37: Asterisk, increment y P o s by the value of. Line 38: Asterisk, the constant local variable RACER underscore SPACE. Line 39: Asterisk. Line 40: Asterisk, if input is anything other than, single quote, T, single quote, comma, single quote, t, single quote. Line 41: Asterisk, single quote, H, single quote, or single quote, h, single quote, do nothing. Line 42: Asterisk, Forward slash. Line 43: 2 forward slashes, write your switch statement here. Line 44: Forward slash, 2 asterisks, end of student code, part 1 Asterisk, Forward slash. Line 45: Right brace. 2 forward slashes, end prepare To Race.

Back to Code

Line 1: Forward slash, 2 asterisks, get Ready method. Line 2: Asterisk, at symbol param g c Graphics Context

context. Line 3: Asterisk, draws the finish line and draws the racers. Line 4: Asterisk, Forward slash. Line 5: protected void get Ready, left parentheses, Graphics Context g c, right parentheses. Line 6: Left brace. Line 7: 2 forward slashes, draw the finish line. Line 8: finish X equals, left parentheses, int, right parentheses. canvas dot get Width, left parentheses, right parentheses hyphen 20, semicolon. The A P I is as follows: public double get Amount, left parentheses, right parentheses.

Back to Code

The A P I is as follows: public void animate, left parentheses, Transaction current Transaction, comma, double current Balance, right parentheses.

Back to Code

The method call is as follows: animate, left parentheses, transaction Object, comma, balance, right parentheses, semicolon.

Back to Code

Line 1: Withdrawal w 2, equals, new Withdrawal, left parentheses, negative 200.00, right parentheses, semicolon. Line 2: transaction List dot add, left parentheses, w 2, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, class, extends, String. Line 1: public class

Exception Name extends Existing Exception Class Name. Line 2: left brace. Line 3, indented once: public Exception Name, left parentheses, String message, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: super, left parentheses, message, right parentheses, semicolon. Line 6, indented once: right brace. Line 7: right brace.

Back to Code

Line 1: access Modifier data Type method Name, left parentheses, parameter list, right parentheses. Line 2, indented multiple times: throws Exception Name. Line 3: left brace. Line 4, indented once: if, left parentheses, parameter list is legal, right parentheses. Line 5, indented twice: 2 forward slashes, process the parameter list. Line 6, indented once: else. Line 7, indented twice: throw new Exception Name, left parentheses, double quotes, Some message here, double quotes, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: try, new, String, while, catch. Line 1: try. Line 2: left brace. Line 3, indented once: Scanner file, equals, new Scanner, left parentheses, new File, left parentheses, double quotes, words dot t x t, double quotes, right parentheses, right parentheses, semicolon. Line 4, indented once: String result, equals, double quotes, double quotes, semicolon. Line 5, indented once: while, left parentheses, file dot has Next, left parentheses, right parentheses, right parentheses. Line 6, indented once: left brace. Line 7, indented twice: String s, equals, file dot next, left parentheses, right parentheses, semicolon. Line 8, indented twice: result, plus, equals, s, semicolon. Line 9, indented twice: result, plus, equals, double quotes, AND, double quotes, semicolon. Line 10, indented once: right brace. Line 11, indented once: System dot out dot print l n, left parentheses, double quotes, result is, double quotes, plus, result, right parentheses, semicolon. Line 12, indented once: file dot close, left parentheses, right parentheses, semicolon. Line 13: right brace.

Back to Code

Line 1: Scanner parse, equals, new Scanner, left parentheses, double quotes, uppercase a, blank space, uppercase b, blank space, uppercase c, blank space, uppercase d, double quotes, right parentheses, semicolon. Line 2: while, left parentheses, parse dot has Next, left parentheses, right parentheses, right parentheses. Line 3, indented once: System dot out dot print, left parentheses, parse dot next, left parentheses, right parentheses, right parentheses, semicolon.

Back to Code

Line 1: Scanner parse, equals, new Scanner, left parentheses, double quotes, uppercase a, uppercase a, colon, uppercase b, uppercase b, colon, uppercase c, uppercase c, double quotes, right parentheses, semicolon. Line 2: parse dot use Delimiter, left parentheses, double quotes, colon, double quotes, right parentheses, semicolon. Line 3: while, left parentheses, parse dot has Next, left parentheses, right parentheses, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, parse dot next, left parentheses, right parentheses, right parentheses, semicolon.

Back to Code

Line 1: Scanner parse, equals, new Scanner, left parentheses, double quotes, one AND two AND three AND four, double quotes, right parentheses, semicolon. Line 2: parse dot use Delimiter, left parentheses, double quotes, AND, double quotes, right parentheses, semicolon. Line 3: while, left parentheses, parse dot has Next, left parentheses, right parentheses, right parentheses. Line 4, indented once: System dot out dot print l n, left parentheses, parse dot next, left parentheses, right parentheses, right parentheses, semicolon.

Back to Code

Line 1: uppercase a. Line 2: uppercase b. Line 3: uppercase c. Line 4: uppercase a. Line 5: uppercase b. Line 6: uppercase a.

Back to Code

Program code. The code contains the following keywords: try, long, catch. Line 1: try. Line 2: left brace. Line 3, indented once: Stream, left angled bracket, String, right angled bracket, data Stream, equals, Files dot lines, left parentheses, Paths dot get, left parentheses, double quotes, data dot t x t, double quotes, right parentheses, right parentheses, semicolon. Line 4, indented once: long count, equals, data Stream dot filter, left parentheses, letter, hyphen, right angled bracket, letter dot char At, left parentheses, equals, equals, single quote, uppercase a, single quote, right parentheses. Line 5, indented multiple times: dot count, left parentheses, right parentheses, semicolon. Line 6, indented once: System dot out dot print l n, left parentheses, double quotes, count, equals, double quotes, plus, count, right parentheses, semicolon. Line 7: right brace. Line 8: blank. Line 9: catch, left parentheses, Invalid Path Exception i p e, right parentheses. Line 10: left brace. Line 11, indented once: System dot out dot print l n, left parentheses, i p e dot get Message, left parentheses, right parentheses, right parentheses, semicolon. Line 12: right brace. Line 13: blank. Line 14: catch, left parentheses, I O Exception i o e, right parentheses. Line 15: left brace. Line 16, indented once: System dot out dot print l n, left parentheses, i o e dot get Message, left parentheses, right parentheses, right parentheses, semicolon. Line 17: right brace. Line 18: blank. Line 19: catch, left parentheses, Security Exception s e, right parentheses. Line 20: left brace. Line 21, indented once: System dot out dot print l n, left parentheses, s e dot get Message, left parentheses, right parentheses, right parentheses, semicolon. Line 22: right brace.

Back to Code

Program code. The code contains the following keywords: try, int, new, while, String, if, catch. Line 1: try. Line 2: Left brace. Line 3, indented once: Scanner file, equals, new Scanner, left parentheses, new File, left parentheses, double quotes, data dot t x t, double quotes, right parentheses, right parentheses, semicolon. Line 4: blank. Line 5, indented once: int n equals 0, semicolon. Line 6, indented once: while, left parentheses, file dot has Next, left parentheses, right parentheses, right parentheses. Line 7, indented once: left brace. Line 8, indented twice: String s, equals, file dot next Line, left parentheses, right parentheses, semicolon. Line 9: blank. Line 10, indented twice: if, left parentheses, s dot equals, left parentheses, double quotes, uppercase a, double quotes, right parentheses, right parentheses. Line 11, indented thrice: n plus, plus, semicolon. Line 12, indented once: right brace. Line 13: blank. Line 14, indented once: System dot out dot print l n, left parentheses, double quotes, The value of n is, double quotes, plus, n, right parentheses, semicolon. Line 15, indented once: file dot close, left parentheses, right parentheses, semicolon. Line 16: right brace. Line 17: catch, left parentheses, I O Exception i o e, right parentheses. Line 18: left brace. Line 19, indented once: i o e dot print Stack Trace, left parentheses, right parentheses, semicolon. Line 20: right brace.

Back to Code

Program code. The code contains the following keywords: try, new, while, String, if, else, catch. Line 1: try. Line 2: left brace. Line 3, indented once: Scanner file, equals, new Scanner, left parentheses, new File, left parentheses, double quotes, data dot t x t, double quotes, right parentheses, right parentheses, semicolon. Line 4: blank. Line 5, indented once: while, left parentheses, file dot has Next, left parentheses, right parentheses, right parentheses. Line 6, indented once: left brace. Line 7, indented twice: String s, equals, file dot next Line, left parentheses, right parentheses, semicolon. Line 8, indented twice: if, left parentheses, s dot equals, left parentheses, double quotes, uppercase a, double quotes, right parentheses, right parentheses. Line 9, indented thrice: System dot out dot print l n, left parentheses, double quotes, Excellent, double quotes, right parentheses, semicolon. Line 10, indented twice: else if, left parentheses, s dot equals, left parentheses, double quotes, uppercase b, double quotes, right parentheses, right parentheses. Line 11, indented thrice: System dot out dot print l n, left parentheses, double quotes, Good, double quotes, right parentheses, semicolon. Line 12, indented twice: else. Line 13, indented thrice: System dot out dot print l n, left parentheses, double quotes, Try to do better, double quotes, right parentheses, semicolon. Line 14, indented once: right brace. Line 15, indented once: file dot close, left parentheses, right parentheses, semicolon. Line 16: right brace. Line 17: catch, left parentheses, I O Exception i o e, right parentheses. Line 18: left brace. Line 19, indented once: i o e dot print Stack Trace, left parentheses, right parentheses, semicolon. Line 20: right brace.

Back to Code

Program code. The code contains the following keywords: try, new, String, while, if, catch. Line 1: try. Line 2: left brace. Line 3, indented once: Scanner file, equals, new Scanner, left parentheses, new File, left parentheses, double quotes, data dot t x t, double quotes, right parentheses, right parentheses, semicolon. Line 4: blank. Line 5, indented once: String s, equals, double quotes, double quotes, semicolon. Line 6, indented once: while, left parentheses, file dot has Next, left parentheses, right parentheses, right parentheses. Line 7, indented once: left brace. Line 8, indented twice: s equals file dot next Line, left parentheses, right parentheses, semicolon. Line 9, indented once: right brace. Line 10: blank. Line 11, indented once: if, left parentheses, s dot equals, left parentheses, double quotes, uppercase a, double quotes, right parentheses, right parentheses. Line 12, indented twice: System dot out dot print l n, left parentheses, double quotes, Nice finish, double quotes, right parentheses, semicolon. Line 13, indented once: file dot close, left parentheses, right parentheses, semicolon. Line 14: right brace. Line 15: catch, left parentheses, I O Exception i o e, right parentheses. Line 16: left brace. Line 17, indented once: i o e dot print Stack Trace, left parentheses, right parentheses, semicolon. Line 18: right brace.

Back to Code

Program code. The code contains the following keywords: try, new, catch. Line 1: try. Line 2: left brace. 3, indented once: Scanner file, equals, new Scanner, left parentheses, new File, left parentheses, double quotes, data t x t, double quotes, right parentheses, right parentheses, semicolon. Line 4: blank. Line 5, indented once: String s, equals, file dot next Line, left parentheses, right parentheses, semicolon. Line 6, indented once: System dot out dot print l n, left parentheses, double quotes, Line read is, double quotes, plus, s, right parentheses, semicolon. Line 7: right brace. Line 8: catch, left parentheses, I O Exception i o e, right parentheses. Line 9: left brace. Line 10, indented once: System dot out dot print l n, left parentheses, i o e dot get Message, left parentheses, right parentheses, right parentheses, semicolon. Line 11: right brace.

Back to Code

The output is as follows: data t x t, left parentheses, The system cannot find the file specified, right parentheses.

Back to Code

Program code. The code contains the following keywords: import, public, class, static, void, String, new. Line 1: import java dot i o dot asterisk, semicolon. Line 2: public class Test. Line 3: left brace. Line 4, indented once: public static void main, left parentheses, String, left square bracket, right square bracket, a r g s, right parentheses. Line 5, indented once: left brace. Line 6, indented twice: File Writer f w, equals, new File Writer, left parentheses, double quotes, data dot t x t, double quotes, comma, false, right parentheses, semicolon. Line 7, indented twice: Print Writer p w, equals, new Print Writer, left parentheses, f w, right parentheses, semicolon. Line 8: blank. Line 9, indented twice: p w dot print l n, left parentheses, double quotes, hi, double quotes, right parentheses, semicolon. Line 10, indented twice: p w dot close, left parentheses, right parentheses, semicolon. Line 11, indented once: right brace. Line 12: right brace.

Back to Code

Line 1: Test dot java, colon, 7, colon, error, colon, unreported exception I O Exception, semicolon, must be. Line 2: caught or declared to be thrown. Line 3, indented once: File Writer f w, equals, new File Writer, left parentheses, double quotes, data dot t x t, double quotes, comma, false, right parentheses, semicolon. Line 4: a caret sign under n of new in Line 3. Line 5: 1 error.

Back to Code

first, equals, Mike, ampersand, last, equals, Jones, ampersand, i d, equals, mike 1, ampersand, password, equals, hello.

Back to Code

Line 1: first, colon, Mike. Line 2: last, colon, Jones. Line 3: i d, colon, mike 1. Line 4: password, colon, hello.

Back to Code

The pseudocode contains the following keywords: void, int, if, else. Line 1: void print Hello World N Times, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, n is greater than 0, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: print, double quotes, Hello World, double quotes. Line 6, indented twice: print Hello World N Times, left parentheses, n minus 1, right parentheses. Line 7, indented once: right brace. Line 8, indented once: 2 forward slashes, else do nothing. Line 9: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, return. Line 1: public static int multiply Absolute Value By 3, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: return, left parentheses, 3 asterisk Math dot a b s, left parentheses, n, right parentheses, right parentheses, semicolon. Line 4: right brace.

Back to Code

return, left parentheses, expression including a recursive call to the method, right parentheses, semicolon.

Back to Code

factorial, left parentheses, n, right parentheses, equals, n factorial, equals, n asterisk, left parentheses, n minus 1, right parentheses, asterisk, left parentheses, n minus 2, right parentheses, asterisk, left parentheses, n minus 3, right parentheses, asterisk, dot, dot, dot, asterisk, 2, asterisk, 1.

Back to Equation

factorial, left parentheses, 0, right parentheses, equals, 0 factorial, equals, 1.

Back to Equation

factorial, left parentheses, n minus 1, right parentheses, equals, left parentheses, n minus 1, right parentheses, factorial, equals, left parentheses, n minus 1, right parentheses, asterisk, left parentheses, n minus 2, right parentheses, asterisk, left parentheses, n minus 3, right parentheses, asterisk, dot, dot, dot, asterisk, 2, asterisk, 1.

Back to Equation

factorial, left parentheses, n, right parentheses, equals, n asterisk factorial, left parentheses, n minus 1, right parentheses.

Back to Equation

5 factorial, equals, 5 asterisk 4 asterisk 3 asterisk 2 asterisk 1, equals, 120.

Back to Equation

Program code. The code contains the following keywords: public, static, int, return. Line 1: public static int factorial, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n must be a positive integer. Line 4, indented once: return, left parentheses, n asterisk factorial, left parentheses, n minus 1, right parentheses, right parentheses, semicolon. Line 5: right brace.

Back to Code

Step 1 is as follows. Line 1: r 0, equals, a, percentage sign, b. Line 2: if, left parentheses, r 0 is equal to 0, right parentheses. Line 3, indented once: g c d, left parentheses, a, comma, b, right parentheses, equals, b. Line 4, indented once: stop. Line 5: else. Line 6, indented once: go to step 2. Step 2 is as follows. Line 1: repeat step 1 with b and r 0, instead of a and b.

Back to Code

Step 1 is as follows. Line 1: r 0, equals, 50, percentage sign, 20, equals, 10. Line 2: is 10 equal to 0, question mark, no, go to Step 2. Step 2 is as follows. Line 1: r 0, equals, 20, forward slash, 10, equals, 0. Line 2: is 0 equal to 0, question mark. Line 3, indented once: yes dot g c d, left parentheses, 50, comma, 20, right parentheses, equals, 10. Line 4, indented once: stop.

Back to Code

The formula reads: Combinations, left parentheses, n, comma, p, right parentheses, equals, Combinations, left parentheses, n minus 1, comma, p minus 1, right parentheses, plus, Combinations, left parentheses, n minus 1, comma, p, right parentheses.

Back to Code

Combinations, left parentheses, n, comma, p, right parentheses, equals, n exclamation mark, forward slash, left parentheses, left parentheses, n minus p, right parentheses, exclamation mark, asterisk, p, exclamation mark, right parentheses.

Back to Equation

Combinations, left parentheses, 5, comma, 2, right parentheses, equals, 5 exclamation mark, forward slash, left parentheses, 3, exclamation mark, asterisk, 2, exclamation mark, right parentheses, equals, 10.

Back to Equation

Combinations, left parentheses, n, comma, p, right parentheses, equals, Combinations, left parentheses, n minus 1, comma, p minus 1, right parentheses, plus, Combinations, left parentheses, n minus 1, comma, p, right parentheses.

Back to Equation

n exclamation mark, forward slash, left parentheses, left parentheses, n minus p, right parentheses, exclamation mark, asterisk, p, exclamation mark, right parentheses, equals, left parentheses, n minus 1, right parentheses, exclamation mark, forward slash, left parentheses, left parentheses, n minus p, right parentheses, exclamation mark, asterisk, left parentheses, p minus 1, right parentheses, exclamation mark, right parentheses, plus, left parentheses, n minus 1, right parentheses, exclamation mark, forward slash, left parentheses, left parentheses, n minus 1 minus p, right parentheses, exclamation mark, asterisk, p, exclamation mark, right parentheses.

Back to Equation

The table has 2 rows labeled Value and Index. The column entries are as follows. Column 1. Value: 12. Index: 0. Column 2. Value: 8. Index: 1. Column 3. Value: 10. Index: 2. Column 4. Value: 5. Index: 3. Columns 2 and 3 are shaded.

Back to Table

The table has 2 rows labeled Value and Index. The column entries are as follows. Column 1. Value: 10. Index: 0. Column 2. Value: 54. Index: 1. Column 3. Value: 23. Index: 2. Column 4. Value: 15. Index: 3. Column 5.

Value: 66. Index: j equals 4. Column 6. Value: 75. Index: 5. Column 7. Value: 98. Index: 6. Column 8. Value: 80. Index: 7. Columns 1 to 4 are shaded blue. Column 5 is shaded red. Columns 6 to 8 are shaded brown.

Back to Table

Line 1: System dot out dot print l n, left parentheses, double quotes, quick Sort, left parentheses, double quotes, plus, start, plus, double quotes, comma, double quotes, plus, end, plus, double quotes, right parentheses, called, double quotes, right parentheses, semicolon. Line 2: System dot out dot print l n, left parentheses, double quotes, partition, left parentheses, double quotes, plus, start, plus, double quotes, comma, double quotes, plus, end, plus, double quotes, right parentheses, called, double quotes, right parentheses, semicolon.

Back to Code

Chapter Review of the book. The background image shows a tunnel like path through a forest.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo 1, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, n equals equals 0, right parentheses. Line 4, indented twice: return 0, semicolon. Line 5, indented once: else if, left parentheses, n greater than 0, right parentheses. Line 6, indented twice: return foo 1, left parentheses, n minus 1, right parentheses, semicolon. Line 7, indented once: else. Line 8, indented twice: return foo 1, left parentheses, n plus 1, right parentheses, semicolon. Line 9: right brace.

Back to Code

int i equals foo 1, left parentheses, 0, right parentheses, semicolon.

Back to Code

int i equals foo 1, left parentheses, 4, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo 2, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, n less than 10, right parentheses. Line 5, indented twice: return n, semicolon. Line 6, indented once: else. Line 7, indented twice: return foo 2, left parentheses, n minus 10, right parentheses, semicolon. Line 11: right brace.

Back to Code

int i equals foo 2, left parentheses, 7, right parentheses,

semicolon.

Back to Code

int i equals foo 2, left parentheses, 13, right parentheses, semicolon.

Back to Code

int i equals foo 2, left parentheses, 65, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, static, void, String, if. Line 1: public static void foo 3, left parentheses, String s, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, s dot length, left parentheses, right parentheses, greater than 0, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: System dot out dot print, left parentheses, s dot char At, left parentheses, s dot length, left parentheses, right parentheses, minus, 1, right parentheses, right parentheses, semicolon. Line 6, indented twice: foo 3, left parentheses, s dot sub string, left parentheses, 0, comma, s dot length, left parentheses, right parentheses, minus 1, right parentheses, right parentheses, semicolon. Line 7, indented once: right brace. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo 4, left parentheses, int n, comma, int p, right parentheses. Line 2: left parentheses. Line 3, indented once: 2 forward slashes, p is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, p equals equals 0, right parentheses. Line 5, indented twice: return 1, semicolon. Line 6, indented once: else. Line 7, indented twice: return, left parentheses, n, asterisk, foo 4, left parentheses, n, comma, p minus 1, right parentheses, right parentheses, semicolon. Line 8: right brace.

Back to Code

int i equals foo 4, left parentheses, 6, comma, 0, right parentheses, semicolon.

Back to Code

int i equals foo 4, left parentheses, 5, comma, 1, right parentheses, semicolon.

Back to Code

int i equals foo 4, left parentheses, 4, comma, 3, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, static, int, String, char, if, else, return. Line 1:

public static int foo, left parentheses, String s, comma, char c, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, s dot length, left parentheses, right parentheses, equals equals, 0, right parentheses. Line 4, indented twice: return 0, semicolon. Line 5, indented once: else. Line 6, indented once: left brace. Line 7, indented twice: 2 forward slashes, your code goes here. Line 8, indented once: right brace. Line 9: right brace.

Back to Code

Program code. The code contains the following keywords: public static String foo, left parentheses, String s, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, s dot length, left parentheses, right parentheses, equals, equals, 0, right parentheses. Line 4, indented twice: return, double quotes, even, double quotes, semicolon. Line 5, indented once: else if, left parentheses, s dot length, left parentheses, right parentheses, equals, equals, 1, right parentheses. Line 6, indented twice: return, double quotes, odd, double quotes, semicolon. Line 7, indented once: else. Line 8, indented twice: 2 forward slashes, your code goes here. Line 9: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: public static int foo, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes. n is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, n equals equals 0, right parentheses. Line 5, indented twice: return 0, semicolon. Line 6, indented once: else. Line 7, indented once: left brace. Line 8, indented twice: 2 forward slashes, your code goes here. Line 9, indented once: right brace. Line 10: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, boolean, String, if, else, return. Line 1: public static boolean foo, left parentheses, String s, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, blank spaces, right parentheses. 2 forward slashes, base case, hash, 1. Line 4, indented once: else if, left parentheses, blank spaces, right parentheses. 2 forward slashes, base case, hash, 2. Line 5, indented once: else. 2 forward slashes, general case. Line 6, indented twice: return foo, left parentheses, s dot substring, left parentheses, 1, comma, s dot length, left parentheses, right parentheses, right parentheses, right parentheses, semicolon. Line 7: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else. Line 1: public static int foo, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than 1. Line 4, indented once: if, left parentheses, n greater than or equal to 1000, right parentheses. 2 forward slashes, base case. Line 5: blank. Line 6, indented once: else. 2 forward slashes, general case. Line 7: right brace.

Back to Code

Program code. The code contains the following keywords: int, public, static, int, if, else, return. Line 1: int p equals foo, left parentheses, 4, right parentheses, semicolon. Line 2: 2 forward slashes, more code here. Line 3: blank. Line 4: public static int foo, left parentheses, int n, right parentheses. Line 5: left brace. Line 6, indented once: int p equals foo, left parentheses, n minus 1, right parentheses, semicolon. Line 7, indented once: if, left parentheses, n equals equals 0, right parentheses. Line 8, indented twice: return 1, semicolon. Line 9, indented once: else. Line 10, indented twice: return, left parentheses, n asterisk p, right parentheses, semicolon. Line 11: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, double, int, if, else, return. Line 1: public static double foo, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: if, left parentheses, n equals equals 0, right parentheses. Line 4, indented twice: return 1.0, semicolon. Line 5, indented once: else if, left parentheses, n less than 0, right parentheses. Line 6, indented twice: return foo, left parentheses, n minus 1, right parentheses, semicolon. Line 7, indented once: else. Line 8, indented twice: return foo, left parentheses, n plus 1, right parentheses, semicolon.

Back to Code

Program code. The code contains the following keywords: public, static, boolean, int, if, else, return, true. Line 1: public static boolean foo, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 0. Line 4, indented once: if, left parentheses, n equals equals 0, right parentheses. Line 5, indented twice: return true, semicolon. Line 6, indented once: else. Line 7, indented twice: foo, left parentheses, n minus 1, right parentheses, semicolon. Line 8: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, boolean, int, if, else, return, true. Line 1: public static boolean foo, left parentheses, int n, right parentheses. Line 2: left brace. Line 3, indented once: 2 forward slashes, n is guaranteed to be greater than or equal to 0. Line 3, indented once: if, left parentheses, n equals equals 0, right parentheses. Line 4, indented twice: return true, semicolon. Line 5, indented once: else. Line 6, indented twice: return foo, left parentheses, n, right parentheses, semicolon. Line 7: right brace.

Back to Code

Program code. The code contains the following keywords: public, static, int, return. Line 1: 2 forward slashes, inside main. Line 2: System dot out dot print l n, left parentheses, foo, left parentheses, 5, right parentheses, right parentheses, semicolon. Line 3: 2 forward slashes, more code here. Line 4: blank. Line 5: public static int foo, left parentheses, int n, right parentheses. Line 6: left brace. Line 7, indented once: return, left parentheses, n asterisk foo, left parentheses, n minus 1, right parentheses, right parentheses, semicolon. 2 forward slashes, line 15. Line 8: right brace.

Back to Code

Line 1: Exception in thread, double quotes, main, double quotes, java dot lang dot Stack Overflow Error. Line 2: at Test dot foo, left parentheses, Test dot java, colon, 15, right parentheses. Line 3: at Test dot foo, left parentheses, Test dot java, colon, 15, right parentheses. Line 4: at Test dot foo, left parentheses, Test dot java, colon, 15, right parentheses. Line 5: dot, dot, dot, dot.

Back to Code

Program code. The code contains the following keywords: public, static, int, if, else, return. Line 1: 2 forward slashes, inside main. Line 2: System dot out dot print l n, left parentheses, foo, left parentheses, 5, right parentheses, right parentheses, semicolon. Line 3: 2 forward slashes, more code here. Line 4: blank. Line 8, indented once: right brace. Line 9, indented once: else. Line 10, indented twice: return false, semicolon. Line 11: right brace.

Back to Code

Program code. The code contains the following keywords: public, throws, if, else, return, throw, new. Line 1: public Player dequeue, left parentheses, right parentheses, throws Data Structure Exception. Line 2: left brace. Line 3, indented once: if, left parentheses, exclamation mark, is Empty, left parentheses, right parentheses, right parentheses. Line 4, indented once: left brace. Line 5, indented twice: front, equals, left parentheses, front plus 1, right parentheses, percentage sign, QUEUE underscore SIZE, semicolon. Line 6, indented twice: number Of Items, minus, minus, semicolon. Line 7, indented twice: return queue, left square bracket, left parentheses, front minus 1, right parentheses, percentage sign, QUEUE underscore SIZE, right square bracket, semicolon. Line 8, indented once: right brace. Line 9, indented once: else. Line 10, indented twice: throw new Data Structure Exception. Line 11, indented multiple times: left parentheses, double quotes, Queue empty, colon, cannot dequeue, double quotes, right parentheses, semicolon. Line 12: right brace.

Back to Code

Line 1: Player Node p n, equals, new, Player Node, left parentheses, right parentheses, semicolon. Line 2: Player p, equals, p n, dot, get Player, left parentheses, right parentheses, semicolon. Line 3: p dot set I D, left parentheses, 10, right parentheses, semicolon. 2 forward slashes, line 10.

Back to Code

Line 1: Exception in thread, double quotes, main, double quotes, java dot lang dot Null Pointer Exception, colon. Line 2: Cannot invoke, double quotes, Player dot set I D, left parentheses, int, right parentheses, double quotes, because, double quotes, left angled bracket, local 2, right angled bracket, double quotes, is null. Line 3, indented multiple times: at Test dot main, left parentheses, Test dot java, colon, 10, right parentheses.

Back to Code

Line 1: Player p, equals, new Player, left parentheses, 5, comma, double quotes, Ajay, double quotes, comma, double quotes, Mario, double quotes, right parentheses, semicolon. Line 2: Player Linked List p l l, equals, new Player Linked List, left parentheses, right parentheses, semicolon. Line 3: p l l dot insert, left parentheses, p, right parentheses, semicolon. Line 4: Player Node temp, equals, p l l dot get Head, left parentheses, right parentheses, semicolon. 2 forward slashes, line 10. Line 5: System dot out dot print l n, left parentheses, double quotes, head is, double quotes, plus, temp dot to String, left parentheses, right parentheses, right parentheses, semicolon.

Back to Code

Line 1: Test dot java, colon, 10, colon, error, colon, cannot find symbol. Line 2, indented once: Player Node temp, equals, p l l dot get Head, left parentheses, right parentheses, semicolon. 2 forward slashes, line 10. Line 3: a caret sign under the dot folling p l l in Line 2. Line 3, indented once: symbol, colon, method get Head, left parentheses, right parentheses. Line 4, indented once: location, colon, variable p l l of type Player Linked List. Line 5: 1 error.

Back to Code

Line 1: Player, p, equals, new, Player, left parentheses, 5, comma, double quotes, Ajay, double quotes, comma, double quotes, Mario, double quotes, right parentheses, semicolon. Line 2: Player Linked List p l l, equals, new Player Linked List, left parentheses, right parentheses, semicolon. Line 3: p l l dot insert, left parentheses, p, right parentheses, semicolon. Line 4: if, left parentheses, p l l dot delete, left parentheses, 5, right parentheses, right parentheses. 2 forward slashes, line 10. Line 5, indented once: System dot out dot print l n, left parentheses, double quotes, Successful deletion, double quotes, right parentheses, semicolon.

Back to Code

Line 1: Test dot java, colon, 10, colon, error, colon, incompatible types, colon, Player cannot be. Line 2: converted to boolean. Line 3, indented once: if, left parentheses, p l l dot delete, left parentheses, 5, right parentheses, right parentheses. 2 forward slashes, line 10. Line 4: A caret sign uner the left parentheses to the left of 5. Line 5: 1 error.

Back to Code

Line 1: Player Node current, equals, head, semicolon. 2 forward slashes, line 9. Line 2: while, left parentheses, current dot get Player, left parentheses, right parentheses, dot, get I D, left parentheses, right parentheses, exclamation mark, equals, 99, right parentheses. Line 3, indented once: current, equals, current dot get Next, left parentheses, right parentheses, semicolon. Line 4: 2 forward slashes, more code here but no problem.

Back to Code

Line 1: Exception in thread, double quotes, main, double quotes, java dot lang dot Null Pointer Exception, colon. Line 2: Cannot invoke, double quotes, Player Node dot get Player, left parentheses, right parentheses, double quotes, because, double quotes, left angled bracket, local 1, right angled bracket, double quotes, is null. Line 3, indented multiple times: at Player Linked List dot foo, left parentheses, Player Linked List dot java, colon, 10, right parentheses. Line 4, indented multiple times: at Test dot main, left parentheses, Test dot java, colon, 24, right parentheses.

Back to Code

The value of L as a function of n if there are n nodes in a binary tree whose deepest level is L. n equals total number of nodes equals sum of nodes for all levels equals 1 plus 2 to the power of 1 plus 2 to the power of 2 plus 2 to the power of 3 plus 2 to the power of 4 plus 2 to the power of 5 plus and so on until 2 to the power of L.

Back to Equation

A simple proof for the formula. n equals equals 1 plus 2 to the power of 1 plus 2 to the power of 2 plus 2 to the power of 3 plus 2 to the power of 4 plus 2 to the power of 5 plus and so on until 2 to the power of L.

Back to Equation

Multiplying each side of the formula by 2. 2 n, 2 plus 2 to the power of 2 plus 2 to the power of 2 plus 2 to the power of 3 plus 2 to the power of 4 plus 2 to the power of 5 plus and so on plus 2 the power of L plus 2 to the power of L plus 1 the whole.

Back to Equation

Subtracting n from 2 n in the formula. 2 n minus n equals 2 to the power of L plus 1 the whole minus 1. Thus, n equals 2 to the power of L plus 1 the whole, or n plus 1 equals 2 the power of L plus 1 the whole.

Back to Equation

Taking the log of both sides of the equation. Log of n plus 1 the whole equals L plus 1, or L equals log of n plus 1 the whole minus 1.

Back to Equation

Method header. Program code. In the code, the words in the variable names are merged. Line 1: private, String, pre Order, left parenthesis, Integer Node, n d, right parenthesis.

Back to Code

Code in question 13 in section 15.10.2. Program code. In the code, the words in the variable names are merged.

Line 1: n d, dot, set Right, left parenthesis, n d, dot, get Right, left parenthesis, right parenthesis, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon.

Back to Code

Code in question 14 in section 15.10.2. Program code. In the code, the words in the variable names are merged. Line 1: Integer Node, temp, equals, n d, dot, get Left, left parenthesis, right parenthesis, dot, get Right, left parenthesis, right parenthesis, semicolon. Line 2: n d, dot, get Left, left parenthesis, right parenthesis, dot, set Right, left parenthesis, temp, dot, get Right, left parenthesis, right parenthesis, right parenthesis, semicolon.

Back to Code

The pre order and in order traversals in a binary tree. In order: 55, 17, 74, 100, 54, 22, 30, 8, 12. Pre order: 100, 17, 55, 74, 22, 54, 8, 30, 12.

Back to Code

The traversals of a binary tree. Pre order: 88, 44, 60, 25, 10, 33, 40, 100. In order: 60, 44, 10, 25, 88, 33, 100, 40. Post order: 60, 10, 25s, 44, 100, 40, 33, 88.

Back to Code

A binary tree. The root node is 50. The node 50 has the child nodes, 30 and 70. The node 30 has the child nodes, 20 and 40. The node 70 has the child node, 90.

Back to Figure

A binary tree. The root node is 10. The node 10 has the child node, 25. The node 25 has the child node, 50. The node 50 has the child node, 75.

Back to Figure

Before and After picture of a traversal in a binary tree. The before picture has the following nodes. The root node is 10. It has the child node, 25. The node 25 has the child node, 50. The node 50 has the child node, 75. The after picture has the following nodes. The root node is 10. It has the child node, 25. The node 25 has the child node, 50.

Back to Code

The exception that is raised by the code in question 34 in section 15.10.5. A Null Pointer Exception is raised. The get Data function cannot be invoked because parameter 1 is null in line number 125 of the code.

Back to Code

Code in question 35 of section 15.10.5. Program code. In the code, the words in the variable names are merged. Line 1: root, dot, set Left, left parenthesis, b t, dot, root, right parenthesis, semicolon.

Back to Code

Code in question 35 of section 15.10.5. Program code. In the code, the words in the variable names are merged. Line 1: root, dot, set Left, left parenthesis, b t, right parenthesis, semicolon.

Back to Code

Error that is raised by the code in question 35 in section 15.10.5. The error is in line number 24 of the Binary Tree dot java program. The error is of incompatible types. Binary Tree cannot be converted to Integer Node in the code, root, dot set Left, left parenthesis, b t, right parenthesis, semicolon.

Back to Code

Code in question 36 of section 15.10.5. Program code. In the code, the words in the variable names are merged. Line 1: public, void, insert, left parenthesis, i n t, value, right parenthesis. Line 2: Left brace. Line 3, indented once: insert, left parenthesis, value, comma, root, right parenthesis, semicolon. Line 4: Right brace.

Back to Code

The exception that is raised by the code in question 36 in section 15.10.5. A Null Pointer Exception is raised. The get Data function cannot be invoked because parameter 2 is null in lines 32, 26, and 11.

Back to Code

A binary tree. The root node is question mark colon 4. The root node has directed edges 0 and 1. Edge 0 points to the node, question mark, colon, 2. Edge 1 points to the node, A, colon, 2. The node question mark, colon, 2 has two directed edges, 0 and 1. Edge 0 points to the node, J, colon, 1. Edge 1 points to the node, V, colon, 1.

Back to Figure

Header pattern for G U I applications. Program code. In the code, the words in the variable names are merged. Line 1: public, class, Class Name, extends, J Frame.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: public, Image Icon, left parenthesis, String, filename, right parenthesis.

Back to Code

The code pattern to use for adding event handling to the Shell G U I Application class. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, import statements as needed. Line 2: public, class, Class Name 1, extends, J Frame. Line 3: Left brace. Line 4, indented once: forward slash, forward slash, declare components and other instance variables. Line 5, indented once: Forward slash, forward slash, constructor. Line 6, indented once: public, Class Name 1, left parenthesis, right parenthesis. Line 7, indented once: Left brace. Line 8, indented twice: Forward slash, forward slash, call J Frame constructor. Line 9, indented twice: forward slash, forward slash, get content pane. Line 10, indented twice: forward slash, forward slash, set the layout manager. Line 11, indented twice: forward slash, forward slash, instantiate components and other instance variables. Line 12, indented twice: forward slash, forward slash, add components to the content pane. Line 13, indented twice: forward slash, forward slash, declare and instantiate event handler objects. Line 14, indented twice: forward slash, forward slash, register event handlers on components. Line 15, indented twice: forward slash, forward slash, set window size. Line 16, indented twice: forward slash, forward slash, make window visible. Line 17, indented once: Right brace. Line 18, indented once: Forward slash, forward slash, private event handler class. Line 19, indented once: private, class, Event Handler Name, implements, Listener Name. Line 20, indented once: Left brace. Line 21, indented twice: forward slash, forward slash, implement the methods of the listener interface. Line 22, indented twice:

forward slash, forward slash, to process the events. Line 23, indented once: Right brace. Line 24, indented once. public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 25, indented once. Left brace. Line 26, indented twice: forward slash, forward slash, instantiate application object. Line 27, indented once: Right brace. Line 28: Right brace.

Back to Code

A compile error. abstract method, action Performed, left parenthesis, Action Event, right parenthesis, in Action Listener. private class Text Field Handler implements Action Listener. 1 error. The error is indicated next to the keyword, class.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: public, String, left parenthesis, char, left square brace, right square brace, char Array, right parenthesis.

Back to Code

Bulk import statement. Program code. In the code, the words in the variable names are merged. Line 1: import, package Name, dot, asterisk, semicolon.

Back to Code

Program code. In the code, the words in the variable names are merged. this, dot, add Mouse Listener, left parenthesis, m h, right parenthesis, semicolon.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: public, class, Controller. Line 2: Left brace. Line 3, indented once: private, Model Interface, model, semicolon, forward slash, forward slash, Model Interface is an interface. Line 4, indented once: private, View, view, semicolon. Line 5, indented once: dot, dot, dot.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: public, class, Model, implements, Model Interface. Line 2: Left brace. Line 3, indented once: forward slash, forward slash, Implements Model Interface methods. Line 4, indented once: dot, dot, dot.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 1: declare a J Panel named top. Line 2: Forward slash, forward slash, also declare three J Button instance variables. Line 3: Forward slash, forward slash, that will be added to the J Panel top. Line 4:

Forward slash, forward slash, these buttons will determine the grid size of the game, colon. Line 5: Forward slash, forward slash, 3-by-3, 4-by-4, or 5-by-5. Line 6: Forward slash, forward slash, task 1 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 2: student code starts here. Line 2: Forward slash, forward slash, instantiate the Border Layout manager b l. Line 3: Forward slash, forward slash, set the layout manager of the content pane contents to b l. Line 4: game, equals, new, Game, left parenthesis, 3, right parenthesis, semicolon, forward slash, forward slash, instantiating the Game object. Line 5: Forward slash, forward slash, add game to the center of the content pane. Line 6: Forward slash, forward slash, task 2 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 3: Student code restarts here. Line 2: Forward slash, forward slash, instantiate the J Panel component named top. Line 3: Forward slash, forward slash, set the layout of top to a 1-by-3 grid. Line 4: Forward slash, forward slash, instantiate the J Buttons that determine the grid size. Line 5: Forward slash, forward slash, add the buttons to J Panel top. Line 6: Forward slash, forward slash, add J Panel top to the content pane as its north component. Line 7: Forward slash, forward slash, task 3 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 4: Student code restarts here. Line 2: Forward slash, forward slash, create a private inner class that implements Action Listener. Line 3: Forward slash, forward slash, your method should identify which of the 3 buttons was the. Line 4: Forward slash, forward slash, source of the event. Line 5: Forward slash, forward slash, depending on which button was pressed, comma. Line 6: Forward slash, forward slash, call the set Up Game method of the Game class. Line 7: Forward slash, forward slash, with arguments 3, 4, or 5. Line 8: Forward slash, forward slash, the A P I of that method is: Line 9: Forward slash, forward slash, public, void, set Up Game, left parenthesis, i n t, n Sides, right parenthesis. Line 10: Forward slash, forward slash, task 4 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 5: Student code restarts here. Line 2: Forward slash, forward slash, Note: search for and complete Task 4 before performing this task. Line 3: Forward slash, forward slash, declare and instantiate an Action Listener. Line 4: Forward slash, forward slash, register the listener on the 3 buttons. Line 5: Forward slash, forward slash, that you declared in Task 1. Line 6: Forward slash, forward slash, task 5 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Grid Layout, g l, equals, new, Grid Layout, left parenthesis, 6, comma, 4, right parenthesis, semicolon.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Border Layout, b l, equals, new, Border Layout, left parenthesis, 7, comma, 3, right parenthesis, semicolon.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: contents, dot, add, left parenthesis, button, comma, Border Layout, dot, NORTH, right parenthesis, semicolon.

Back to Code

Code to consider for questions 16 to 21. Program code. In the code, the words in the variable names are merged.

Line 1: import, java x, dot, swing, dot, asterisk, semicolon. Line 2: import, java, dot, a w t, dot, asterisk, semicolon. Line 3: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 4: public, class, Game, extends, J Frame. Line 5: Left brace. Line 6, indented once: private, J Button, b 1, comma, b 2, comma, b 3, comma, b 4, semicolon. Line 7, indented once: private, Container, contents, semicolon. Line 8, indented once: public, Game, left parenthesis, right parenthesis. Line 9, indented once: Left brace. Line 10, indented twice: super, left parenthesis, open quotes, Play this game, close quotes, right parenthesis, semicolon. Line 11, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 12, indented twice: contents, dot, set Layout, left parenthesis, new, Grid Layout, left parenthesis, 2, comma, 2, right parenthesis, right parenthesis, semicolon. Line 13, indented twice: b 1, equals, new, J Button, left parenthesis, open quotes, Button 1, close quotes, right parenthesis, semicolon. Line 14, indented twice: b 2, equals, new, J Button, left parenthesis, open quotes, Button 2, close quotes, right parenthesis, semicolon. Line 15, indented twice: b 3, equals, new, J Button, left parenthesis, open quotes, Button 3, close quotes, right parenthesis, semicolon. Line 16, indented twice: b 4, equals, new, J Button, left parenthesis, open quotes, Button 4, close quotes, right parenthesis, semicolon. Line 17, indented once: contents, dot, add, left parenthesis, b 1, right parenthesis, semicolon. Line 18, indented twice: contents, dot, add, left parenthesis, b 2, right parenthesis, semicolon. Line 19, indented twice: contents, dot, add, left parenthesis, b 3, right parenthesis, semicolon. Line 20, indented twice: My Handler, m h, equals, new, My Handler, left parenthesis, right parenthesis, semicolon. Line 21, indented twice: b 1, dot, add Action Listener, left parenthesis, m h, right parenthesis, semicolon. Line 22, indented twice: b 2, dot, add Action Listener, left parenthesis, m h, right parenthesis, semicolon. Line 23, indented twice: set Size, left parenthesis, 400, comma, 400, right parenthesis, semicolon. Line 24, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 25, indented once: right brace. Line 26, indented once: private, class, My Handler, implements, Action Listener. Line 27, indented once: Left brace. Line 28, indented twice: public, void, action Performed, left parenthesis, Action Event, a e, right parenthesis. Line 29, indented twice: Left brace. Line 30, indented 3 times: System, dot, out, dot, print l n, left parenthesis, open quotes, Hello, close quotes, right parenthesis, semicolon. Line 31, indented 3 times: if, left parenthesis, a e, dot, get Source, left parenthesis, right parenthesis, equals, equals, b 2, right parenthesis. Line 32, indented 4 times: System, dot, out, dot, print l n, left parenthesis, open quotes, Hello again, close quotes, right parenthesis, semicolon. Line 33, indented twice: right brace. Line 34, indented once: right brace. Line 35, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 36, indented once:

Left brace. Line 37, indented twice: Game, g, equals, new, Game, left parenthesis, right parenthesis, semicolon. Line 38, indented twice: g, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 39, indented once: right brace. Line 40: right brace.

Back to Code

Code to consider for questions 22 to 26. Program code. In the code, the words in the variable names are merged. Line 1: import, java x, dot, swing, dot, asterisk, semicolon. Line 2 import, java, dot, a w t, dot, asterisk, semicolon. Line 3: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 4: public, class, Game, extends, J Frame. Line 5: Left parenthesis. Line 6, indented once: private, J Check Box, c 1, comma, c 2, comma, c 3, semicolon. Line 7, indented once: private, i n t, value 1, comma, value 2, comma, value 3, semicolon. Line 8, indented once: private, Container, contents, semicolon. Line 9, indented once: public, Game, left parenthesis, right parenthesis. Line 10, indented once: Left brace. Line 11, indented twice: super, left parenthesis, open quotes, Play this game, close quotes, right parenthesis, semicolon. Line 12, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 13, indented twice: contents, dot, set Layout, left parenthesis, new, Flow Layout, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 14, indented twice: c 1, equals, new, J Check Box, left parenthesis, open quotes, Choice 1, close quotes, right parenthesis, semicolon. Line 15, indented twice: c 2, equals, new, J Check Box, left parenthesis, open quotes, Choice 2, close quotes, right parenthesis, semicolon. Line 16, indented twice: c 3, equals, new, J Check Box, left parenthesis, open quotes, Choice 3, close quotes, right parenthesis, semicolon. Line 17, indented twice: contents, dot, add, left parenthesis, c 1, right parenthesis, semicolon. Line 18, indented twice: contents, dot, add, left parenthesis, c 2, right parenthesis, semicolon. Line 19, indented twice: contents, dot, add, left parenthesis, c 3, right parenthesis, semicolon. Line 20, indented twice: My Handler, m h, equals, new, My Handler, left parenthesis, right parenthesis, semicolon. Line 21, indented twice: c 1, dot, add Item Listener, left parenthesis, m h, right parenthesis, semicolon. Line 22, indented twice: c 2, dot, add Item Listener, left parenthesis, m h, right parenthesis, semicolon. Line 23, indented twice: c 3, dot, add Item Listener, left parenthesis, m h, right parenthesis, semicolon. Line 24, indented twice: set Size, left parenthesis, 400, comma, 400, right parenthesis, semicolon. Line 25, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 26, indented once: right brace. Line 27, indented once: private, class, My Handler, implements, Item Listener. Line 28, indented once: Left brace. Line 29, indented twice: public, void, item State Changed, left parenthesis, Item Event, i e, right parenthesis. Line 30, indented twice: Left brace. Line 31, indented 3 times: if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, c 1, right parenthesis. Line 32, indented 3 times: Left brace. Line 33, indented 4 times: if, left parenthesis, i e, dot, get State Change, left parenthesis, right parenthesis, equals, equals, equals, equals, Item Event, dot, SELECTED, right parenthesis. Line 34, indented 5 times: value 1, equals, 1, semicolon. Line 35, indented 4 times: else. Line 36, indented 5 times: value 1, equals, 0, semicolon. Line 37, indented 3 times: right brace. Line 38, indented 3 times: else, if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, c 2, right parenthesis. Line 39, indented 3 times: Left brace. Line 40, indented 4 times: if, left parenthesis, i e, dot, get State Change, left parenthesis, right parenthesis, equals, equals, Item Event, dot, SELECTED, right parenthesis. Line 41, indented 5 times: value 2, equals, 2, semicolon. Line 42, indented 4 times: else. Line 43, indented 5 times: value 2, equals, 0, semicolon. Line 44, indented 3 times: right brace. Line 45, indented 3 times: else, if, left parenthesis, i e, dot, get Source, left parenthesis, right parenthesis, equals, equals, c 3, right parenthesis. Line 46, indented 3 times: left brace. Line 47, indented 4 times: if, left parenthesis, i e, dot, get State Change, left parenthesis, right parenthesis, equals, equals, Item Event, dot, SELECTED, right parenthesis. Line 48, indented 5 times: value 3, equals, 4, semicolon. Line 49, indented 4 times: else. Line 50, indented 5 times: value 3, equals, 0, semicolon. Line 51, indented 3 times: right brace. Line 52, indented 3 times:

System, dot, out, dot, print l n, left parenthesis, left parenthesis, value 1, plus, value 2, plus, value 3, right parenthesis, right parenthesis, semicolon. Line 53, indented twice: right brace. Line 54, indented once: right brace. Line 55, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 56, indented once: left brace. Line 57, indented twice: Game, g, equals, new, Game, left parenthesis, right parenthesis, semicolon. Line 58, indented twice: g, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 59, indented once: right brace. Line 60: right brace.

Back to Code

Code to consider for questions 27 to 32. Program code. In the code, the words in the variable names are merged. Line 1: import, java x, dot, swing, dot, asterisk, semicolon. Line 2: import, java, dot, a w t, dot, asterisk, semicolon. Line 3: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 4: public, class, A, extends, J Frame. Line 5: Left brace. Line 6, indented once: private, Container, c, semicolon. Line 7, indented once: private, J Button, b, semicolon. Line 8, indented once: private, J Text Field, t f, semicolon. Line 9: right brace.

Game, close quotes, right parenthesis, semicolon. Line 10, indented twice: c, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 11, indented twice: t f, equals, new, J Text Field, left parenthesis, open quotes, Hello, close quotes, right parenthesis, semicolon. Line 12, indented twice: c, dot, add, left parenthesis, t f, comma, NORTH, right parenthesis, semicolon. Line 13, indented twice: set Size, left parenthesis, 400, comma, 400, right parenthesis, semicolon. Line 14, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 15, indented once: Left brace. Line 16, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 17, indented once: Left brace. Line 18, indented twice: My Game, m g, equals, new, My Game, left parenthesis, right parenthesis, semicolon. Line 19, indented once: right brace. Line 20: Left brace.

Back to Code

The error that is generated when the code in question 48 is compiled. The error indicates that the the variable NORTH in line number 14 of the program My Game dot java cannot be found. Program code. In the code, the words in the variable names are merged. c, dot, add, left parenthesis, t f, comma, NORTH, right parenthesis.

Back to Code

Code in the program My Game dot java. Program code. In the code, the words in the variable names are merged. Line 1: import, java x, dot, swing, dot, asterisk, semicolon. Line 2: import, java, dot, a w t, dot, asterisk, semicolon. Line 3: public, class, My Game, extends, J Frame. Line 4: Left brace. Line 5, indented once: Forward slash, forward slash, Some code here. Line 6, indented once: private, class, My Handler, implements, Action Listener. Line 7, indented once: Left brace. Line 8, indented twice: public, void, action Performed, left parenthesis, Action Event, a e, right parenthesis. Line 9, indented twice: Left brace, right brace. Line 10, indented once: right brace. Line 11: right brace.

Back to Code

The errors that are generated when the code in question 49 is compiled. The first error indicates an error in the keyword Action Listener in line 7 of the program My Game dot java. Line 7 is listed further. Program code. In the code, the words in the variable names are merged. private, class, My Handler, implement, Action Listener. The second error indicates an error in the keywork Action Event in the following line of code in the same program. Program code. In the code, the words in the variable names are merged. public, void, action Preformed, left parenthesis, Action Event, right parenthesis, a e, right parenthesis.

Back to Code

Code for the program My Game dot java in question 50. Program code. In the code, the words in the variable names are merged. Line 1: import, java x, dot, swing, dot, asterisk, semicolon. Line 2: import, java, dot, a w t, dot, asterisk, semicolon. Line 3: import, java, dot, a w t, dot, event, dot, asterisk, semicolon. Line 4: public, class, My Game, extends, J Frame. Line 5: Left brace. Line 6, indented once: private, J Button, b, semicolon. Line 7, indented once: private, J Text Field, t f, semicolon. Line 8, indented once: private, Container, contents, semicolon. Line 9, indented once: public, My Game, left parenthesis, right parenthesis. Line 10, indented once: Left brace. Line 11, indented twice: super, left parenthesis, open quotes, Play this game, close quotes, right parenthesis, semicolon. Line 12, indented twice: contents, equals, get Content Pane, left parenthesis, right parenthesis, semicolon. Line 13, indented twice: contents, dot, set Layout, left parenthesis, new, Grid Layout, left parenthesis, 1, comma, 2, right parenthesis, right parenthesis, semicolon. Line 14, indented twice: b, equals, new, J Button, left parenthesis, open quotes, Click here, close quotes, right parenthesis, semicolon. Line 15, indented twice: t f, equals, new, J Text Field, left parenthesis, open quotes, Hello, close quotes, right parenthesis, semicolon. Line 16, indented twice: contents, dot, add, left parenthesis, b, right parenthesis, semicolon. Line 17, indented twice: contents, dot, add, left parenthesis, t f, right parenthesis, semicolon. Line 18, indented twice: set Size, left parenthesis, 400, comma, 400, right parenthesis, semicolon. Line 19, indented twice: set Visible, left parenthesis, true, right parenthesis, semicolon. Line 20, indented once: right brace. Line 21, indented once: private, class, My Handler implements, Action Listener. Line 22, indented once: Left brace. Line 23, indented twice: public, void, action Performed, left parenthesis, Action Event, a e, right parenthesis. Line 24, indented twice: Left brace. Line 25, indented 3 times: t f, dot, set Text, left parenthesis, open quotes, Hi, close quotes, right parenthesis, semicolon. Line 26, indented twice: right brace. Line 27, indented once: right brace. Line 28, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 29, indented once: Left brace. Line 30, indented twice: My Game, g, equals, new, My Game, left parenthesis, right parenthesis, semicolon. Line 31, indented once: g, dot, set Default Close Operation, left parenthesis, J Frame, dot, EXIT underscore ON underscore CLOSE, right parenthesis, semicolon. Line 32, indented once: right brace. Line 33: right brace.

Back to Code

The positions on a football field displayed as a button. The following positions are listed. Left wing of 11. Striker of 9. Right wing of 7. Left midfielder of 6. Midfielder of 10. Right midfielder of 8. Left defender of 3. Stopper of 4. Sweeper of 5. Right defender of 2. Goalie of 1.

Back to Figure

attribute Name, equals, double quotes, value, double quotes.

Back to Code

attribute Name, equals, single quote, value, single quote.

Back to Code

x m l n s, colon, f x, equals, double quotes, h t t p, colon, 2 forward slashes, java f x dot com, forward slash, f x m l, double quotes.

Back to Code

void calculate, left parentheses, Action Event event, right parentheses.

Back to Code

void changed, left parentheses, Observable Value, left angled bracket, question mark, extends uppercase t, right angled bracket, observable, comma, uppercase t old Value, comma, uppercase t, new Value, right parentheses.

Back to Code

Double quotes, style Attribute 1, colon, value 1, semicolon, style Attribute 2, colon, value 2, semicolon, style Attribute 3, colon, value 3, semicolon, dot, dot, dot, double quotes.

Back to Code

Double quotes, hyphen, f x, hyphen, background, hyphen, color, colon, blue, semicolon, hyphen, f x, hyphen, font, hyphen, size, colon, 25, double quotes.

Back to Code

Program code. The code contains the following keywords: new, public, void, false. Line 1: t dot set On Finished, left parentheses, new Event Handler, left angled bracket, Action Event, right angled bracket, left parentheses, right parentheses. Line 2: left brace. Line 3, indented once: at symbol, Override. Line 4, indented twice: public void handle, left parentheses, Action Event event, right parentheses. Line 5, indented twice: left brace. Line 6, indented thrice: disable Buttons, left parentheses, false, right parentheses, semicolon. Line 7, indented twice: right brace. Line 8, indented once: right brace. Line 9: right brace, semicolon.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: public, class, Controller. Line 2: Left brace. Line 3, indented once: private, Model Interface, model, semicolon, forward slash, forward slash, Model Interface is an interface. Line 4, indented once: private, View, view, semicolon. Line 5, indented once: dot,

dot, dot. Line 6: right brace.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: public, class, Model, implements, Model Interface. Line 2: Left brace. Line 3, indented once: Forward slash, forward slash, Implements Model Interface methods. Line 4, indented once: dot, dot, dot. Line 5: right brace.

Back to Code

The data in the initial two X Y Chart dot Series. Bonds series: “2020”,100.0 “2021”,103.0 “2022”,106.09 “2023”,109.2727. Stocks series: “2020”,100.0 “2021”,107.0 “2022”,114.49 “2023”,122.5043.

Back to Code

The general syntax to style a G U I component in a style sheet. Program code. In the code, the words in the variable names are merged. Line 1: selector. Line 2: left brace. Line 3, indented once: attribute 1, colon, value 1, semicolon. Line 4, indented once: attribute 2, colon, value 2, semicolon. Line 5, indented once: dot, dot, dot. Line 6: right brace.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Line 1: Forward slash, forward slash, a few asterisks, Task 1: declare an H Box named top. Line 2: Forward slash, forward slash, also declare three Button instance variables. Line 3: Forward slash, forward slash, that will be added to the H Box top. Line 4: Forward slash, forward slash, These buttons will determine the grid size of the game: Line 5: Forward slash, forward slash, 3-by-3, 4-by-4, or 5-by-5. Line 6: Forward slash, forward slash, task 1 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 2: student code starts here. Line 2: Forward slash, forward slash, instantiate the Game View object. Line 3: Forward slash, forward slash, add game View to the center of this Border Pane. Line 4: Forward slash, forward slash, task 2 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 3: Student code restarts here. Line 2: Forward slash, forward slash, instantiate the H Box component named top. Line 3: Forward slash, forward slash, instantiate the Buttons that determine the grid size. Line 4: Forward slash, forward slash, add the buttons to H Box top. Line 5: Forward slash, forward slash, make them take all the available space. Line 6: Forward slash, forward slash, add H Box top to this Border Pane as its top component. Line 7: Forward slash, forward slash, task 3 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 4: Student code restarts here. Line 2: Forward slash, forward slash, create a private inner class that implements Event Handler. Line 3: Forward slash, forward slash, your method should identify which of the 3 buttons. Line 4: Forward slash, forward slash, was the source of the event. Line 5: Forward slash, forward slash, depending on which button was pressed, Line 6: Forward slash, forward slash, call the set Up Game method of the Game View class. Line 7: Forward slash, forward slash, with arguments 3, 4, or 5. Line 8: Forward slash, forward slash, the A P I of that method is: Line 9: Forward slash, forward slash, public, void, set Up Game, left parenthesis, i n t, n Sides, right parenthesis. Line 10: Forward slash, forward slash, task 4 ends here.

Back to Code

Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, a few asterisks, Task 5: Student code restarts here. Line 2: Forward slash, forward slash, Note: search for and complete Task 4 before performing this task. Line 3:

Forward slash, forward slash, declare and instantiate an Event Handler. Line 4: Forward slash, forward slash, register the handler on the 3 buttons. Line 5: Forward slash, forward slash, that you declared in Task 1. Line 6: Forward slash, forward slash, task 5 ends here.

Back to Code

Code in F X M L file to consider for questions 21 to 25. Program code. In the code, the words in the variable names are merged. Line 1: Left angle bracket, question mark, x m l, version, equals, open quotes, 1.0, close quotes, encoding, equals, open quotes, U T F hyphen 8, close quotes, question mark, right angle bracket. Line 2: left angle bracket, question mark, import, java f x, dot, scene, dot, control, dot, asterisk, question mark, right angle bracket. Line 3: Left angle bracket, question mark, import, java f x, dot, scene, dot, layout, dot, asterisk, question mark, right angle bracket. Line 4: Left angle bracket, H Box, f x, colon, controller, equals, open quotes, My Controller, close quotes. Line 5, indented a few times: x m l n s, colon, f x, equals, open quotes, h t t p, colon, double slash, java f x, dot, com, forward slash, f x m l, close quotes. Line 6, indented a few times: alignment, equals, open quotes, center, close quotes, spacing, equals, open quotes, 10, close quotes, right angle bracket. Line 7, indented once: left angle bracket, Button, f x, colon, i d, equals, open quotes, button 1, close quotes, text, equals, open quotes, Button 1, close quotes. Line 8, indented a few times: on Action, equals, open quotes, hash, go, close quotes, forward slash, right angle bracket. Line 9, indented once: left angle bracket, Button, f x, colon, i d, equals, open quotes, button 2, close quotes, text, equals, open quotes, Button 2, close quotes. Line 10, indented a few times: on Action, equals, open quotes, hash, go, close quotes, forward slash, right angle bracket. Line 11, indented once: Left angle bracket, Label, f x, colon, i d, equals, open quotes, result, close quotes, forward slash, right angle bracket. Line 12, indented once: Left angle bracket, Button, f x, colon, i d, equals, open quotes, button 3, close quotes, text, equals, open quotes, Button 3, close quotes. Line 13, indented a few times" on Action, equals, open quotes, hash, go, close quotes, forward slash, right angle bracket. Line 14, indented once: Left angle bracket, Button, f x, colon, i d, equals, open quotes, button 4, close quotes, text, equals, open quotes, Button 4, close quotes. Line 15, indented a few times: on Action, equals, open quotes, hash, go, close quotes, forward slash, right angle bracket. Line 16: Left angle bracket, forward slash, H Box, right angle bracket.

Back to Code

Code to consider for questions 26 to 29. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, Controller class. Line 2: Asterisk, Anderson, comma, Franceschi. Line 3: Asterisk, forward slash. Line 4: import, java f x, dot, event, dot, Action Event, semicolon. Line 5: import, java f x, dot, f x m l, dot, F X M L, semicolon. Line 6: import, java f x, dot, scene, dot, control, dot, asterisk, semicolon. Line 7: public, class, Controller. Line 8: Left brace. Line 9, indented once: at, F X M L, private, Check Box, c b 1, semicolon. Line 10, indented once: at, F X M L, private, Check Box, c b 2, semicolon. Line 11, indented once: at, F X M L, private, Check Box, c b 3, semicolon. Line 12, indented once: at, F X M L, private, Label, label, semicolon. Line 13, indented once: private, i n t, read, write, execute, semicolon. Line 14, indented once: at, F X M L, protected, void, mix, left parenthesis, Action Event, event, right parenthesis. Line 15, indented once: Left brace. Line 16, indented twice: Check Box, c b, equals, left parenthesis, Check Box, right parenthesis, event, dot, get Source, left parenthesis, right parenthesis, semicolon. Line 17, indented twice: if, left parenthesis, c b, equals, equals, c b 1, right parenthesis. Line 18, indented 3 times: read, equals, left parenthesis, c b, dot, is Selected, left parenthesis, right parenthesis, question mark, 4, colon, 0, right parenthesis, semicolon. Line 19, indented twice: else, if, left parenthesis, c b, equals, equals, c b 2, right parenthesis. Line 20, indented 3 times: write, equals, left parenthesis, c b, dot, is Selected, left parenthesis, right parenthesis, question mark, 2, colon, 0, right parenthesis, semicolon. Line 21, indented twice: else, if, left parenthesis, c b, equals, equals, c b 3, right parenthesis. Line 22, indented 3 times: execute, equals, left parenthesis, c b, dot, is Selected, left parenthesis, right parenthesis, question mark, 1, colon, 0, right parenthesis, semicolon. Line 23, indented twice: i n t, mode, equals, read, plus, write, plus, execute, semicolon. Line 24, indented 3 times: label, dot, set Text, left parenthesis, open quotes, mode, colon, space, close quotes, plus, mode, right parenthesis, semicolon. Line 25, indented once: right brace. Line 26: right brace.

Back to Code

Code to consider for questions 30 to 32. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, event, dot, asterisk, semicolon. Line 2: import, java f x, dot, scene, dot, control, dot, Button, semicolon. Line 3: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 4: public, class, Board View, extends, Grid Pane. Line 5: Left brace. Line 6, indented once: private, Button, left square brace, right square brace, left square brace, right square brace, buttons, semicolon. Line 7, indented once: public, Board View, left parenthesis, right parenthesis. Line 8, indented once: left brace. Line 9, indented twice: super, left parenthesis, right parenthesis, semicolon. Line 10, indented twice: Column Constraints, c o l, equals, new, Column Constraints, left parenthesis, right parenthesis, semicolon. Line 11, indented twice: c o l, dot, set Percent Width, left parenthesis, 25, right parenthesis, semicolon. Line 12, indented twice: Row Constraints, row, equals, new, Row Constraints, left parenthesis, right parenthesis, semicolon. Line 13, indented twice: row, dot, set Percent Height, left parenthesis, 20, right parenthesis, semicolon. Line 14, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, 5, semicolon, i, plus, plus, right parenthesis. Line 15, indented 3 times: get Row Constraints, left parenthesis, right parenthesis, dot, add, left parenthesis, row, right parenthesis, semicolon. Line 16, indented twice: for, left parenthesis, i n t, j, equals, 0, semicolon, j, less than, 4, semicolon, j, plus, plus, right parenthesis. Line 17, indented 3 times: get Column Constraints, left parenthesis, right parenthesis, dot, add, left parenthesis, c o l, right parenthesis, semicolon. Line 18, indented twice: buttons, equals, new, Button, left square brace, 5, right square brace, left square brace, 4, right square brace, semicolon. Line 19, indented twice: Button Handler, b h, equals, new, Button Handler, left parenthesis, right parenthesis, semicolon. Line 20, indented twice: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, 5, semicolon, i, plus, plus, right parenthesis. Line 21, indented twice: Left brace. Line 22, indented 3 times: for, left parenthesis, i n t, j, equals, 0, semicolon, j, less than, 4, semicolon, j, plus, plus, right parenthesis. Line 23, indented 3 times: Left brace. Line 24, indented 4 times: forward slash, forward slash, instantiate the buttons. Line 25, indented 4 times: buttons, left square brace, i, right square brace, left square brace, j, right square brace, equals, new, Button, left parenthesis, right parenthesis, semicolon. Line 26, indented 4 times: buttons, left square brace, i, right square brace, left square brace, j, right square brace, dot, set Max Width, left parenthesis, Double, dot, MAX underscore VALUE, right parenthesis, semicolon. Line 27, indented 4 times: buttons, left square brace, i, right square brace, left square brace, j, right square brace, dot, set Max Height, left parenthesis, Double, dot, MAX underscore VALUE, right parenthesis, semicolon. Line 28, indented a few times: add, left parenthesis, buttons, left square brace, i, right square brace, left square brace, j, right square brace, comma, j, comma, i, right parenthesis, semicolon. Line 29, indented 4 times: buttons, left square brace, i, right square brace, left square brace, j, right square brace, dot, set On Action, left parenthesis, b h, right parenthesis, semicolon. Line 30, indented 3 times: right brace. Line 31, indented twice: right brace. Line 32, indented once: right brace. Line 33, indented once: private, class, Button Handler, implements, Event Handler, left angle bracket, Action Event, right angle bracket. Line 34, indented once: Left brace. Line 35, indented twice: public, void, handle, left parenthesis, Action Event, event, right parenthesis. Line 36, indented twice: left brace. Line 37, indented 3 times: for, left parenthesis, i n t, i, equals, 0, semicolon, i, less than, buttons, dot, length, semicolon, i, plus, plus, right parenthesis. Line 38, indented 4 times: for, left parenthesis, i n t, j, equals, 0, semicolon, j, less than, buttons, left square brace, i, right square brace, dot, length, semicolon, j, plus, plus, right parenthesis. Line 39, indented 5 times: if, left parenthesis, event, dot, get Source, left parenthesis, right parenthesis, equals, equals, buttons, left square brace, i, right square brace, left square brace, j, right square brace, right parenthesis. Line

40, indented 6 times: buttons, left square brace, i, right square brace, left square brace, j, right square brace, dot, set Text, left parenthesis, open quote, close quotes, plus, String, dot, value Of, left parenthesis, i, plus, j, right parenthesis, right parenthesis, semicolon. Line 41, indented twice: right brace. Line 42, indented once: right brace. Line 43: right brace.

Back to Code

Code to consider for questions 33 to 35. Program code. In the code, the words in the variable names are merged. Line 1: Left angle bracket, question mark, x m l, version, equals, open quotes, 1.0, close quotes, encoding, equals, open quotes, U T F hyphen 8, close quotes, question mark, right angle bracket. Line 2: Left angle bracket, question mark, import, java f x, dot, scene, dot, control, dot, asterisk, question mark, right angle bracket Line 3: Left angle bracket, question mark, import, java f x, dot, scene, dot, layout, dot, asterisk, question mark, right angle bracket. Line 4: Left angle bracket, Border Pane, f x, colon, controller, equals, open quotes, My Controller, close quotes. Line 5, indented a few times: x m l n s, colon, f x, equals, open quotes, h t t p, colon, forward slash, forward slash, java f x, dot, com, forward slash, f x m l, close quotes, right angle bracket. Line 6, indented once: Left angle bracket, top, right angle bracket. Line 7, indented twice: Left angle bracket, H Box, alignment, equals, open quotes, center, close quotes, right angle bracket. Line 8, indented 3 times: Left angle bracket, Button, f x, colon, i d, equals, open quotes, button 1, close quotes, text, equals, open quotes, INSERT, close quotes, forward slash, right angle bracket. Line 9, indented twice: Left angle bracket, forward slash, H Box, right angle bracket. Line 10, indented once: left angle bracket, forward slash, top, right angle bracket. Line 11, indented once: Left angle bracket, left, right angle bracket. Line 12, indented twice: Left angle bracket, H Box, alignment, equals, open quotes, center, close quotes, right angle bracket. Line 13, indented 3 times: left angle bracket, Button, f x, colon, i d, equals, open quotes, button 2, close quotes, text, equals, open quotes, UPDATE, close quotes, on Action, equals, open quotes, hash, go, close quotes, forward slash, right angle bracket. Line 14, indented twice: left angle bracket, forward slash, H Box, right angle bracket. Line 15, indented once: Left angle bracket, forward slash, left, right angle bracket. Line 16, indented once: Left angle bracket, exclamation mark, hyphen, hyphen, answer to questions 33 to 35 go here, hyphen, hyphen, right angle bracket. Line 17: Left angle bracket, forward slash, Border Pane, right angle bracket.

Back to Code

Code to consider for questions 36 to 40. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, event, dot, asterisk, semicolon. Line 2: import, java f x, dot, scene, dot, control, dot, asterisk, semicolon. Line 3: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 4:

Back to Code

Program code in question 55. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, event, dot, asterisk, semicolon. Line 2: import, java f x, dot, scene, dot, control, dot, Button, semicolon. Line 3: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 4: public, class, My Game, extends, Grid Pane. Line 5: Left brace. Line 6, indented once: Forward slash, forward slash. some code here. Line 7, indented once: private, class, My Handler, extends, Event Handler, left angle bracket, Action Event, right angle bracket. Line 8, indented once: Left brace. Line 9, indented twice: public, void, handle, left parenthesis, Action Event, a e, right parenthesis. Line 10, indented twice: Left brace, right brace. Line 11, indented once: right brace. Line 12: right brace.

Back to Code

Program code in question 56. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, event, dot, asterisk, semicolon. Line 2: import, java f x, dot, scene, dot, control, dot, Button, semicolon. Line 3: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 4: public, class, My Game, extends, Grid Pane. Line 5: Left brace. Line 6, indented once: Forward slash, forward slash. some code here. Line 7, indented once: private, class, My Handler, implements, Event Handler. Line 8, indented once: Left brace. Line 9, indented twice: public, void, handle, left parenthesis, Action Event, a e, right parenthesis. Line 10, indented twice: Left brace, right brace. Line 11, indented once: right

brace. Line 12: right brace.

Back to Code

Program code in question 57. Program code. In the code, the words in the variable names are merged. Line 1: X Y Chart, dot, Series, left angle bracket, String, comma, Number, right angle bracket, series. Line 2, indented once: equals, new, X Y Chart, dot, Series, left angle bracket, String, comma, Number, right angle bracket, left parenthesis, right parenthesis, semicolon. Line 3: series, dot, add, left parenthesis, new, X Y Chart, dot, Data, left angle bracket, String, comma, Number, right angle bracket, left parenthesis, open quotes, HI, close quotes, comma, 2.0, right parenthesis, right parenthesis, semicolon.

Back to Code

Program code in question 58. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, b c is a Bar Chart and has been instantiated. Line 2: Array List, left angle bracket, X Y Chart, dot, Series, left angle bracket, String, comma, Number, right angle bracket, right angle bracket, series. Line 3, indented once: equals, new, Array List, left angle bracket, X Y Chart, dot, Series, left angle bracket, String, comma, Number, right angle bracket, right angle bracket, right parenthesis, right parenthesis, semicolon. Line 4: Forward slash, forward slash, fill in series here. Line 5: b c, dot, add All, left parenthesis, series, right parenthesis, semicolon.

Back to Code

Program code in question 59. Program code. In the code, the words in the variable names are merged. Line 1: import, java, dot, net, dot, U R L, semicolon. Line 2: import, java f x, dot, application, dot, Application, semicolon. Line 3: import, java f x, dot, f x m l, dot, F X M L Loader, semicolon. Line 4: import, java f x, dot, scene, dot, layout, dot, V Box, semicolon. Line 5: import, java f x, dot, scene, dot, Scene, semicolon. Line 6: import, java f x, dot, stage, dot, Stage, semicolon. Line 7: public, class, Test 59, extends, Application. Line 8: Left brace. Line 9, indented once: at, Override. Line 10, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis. Line 11, indented once: left brace. Line 12, indented twice: try. Line 13, indented twice: Left brace. Line 14, indented 3 times: U R L, u r l, equals, get Class, left parenthesis, right parenthesis, dot, get Resource, left parenthesis, open quotes, f x m l underscore e x 1, dot, f x m l, close quotes, right parenthesis, semicolon. Line 15, indented 3 times: V Box, root, equals, F X M L Loader, dot, load, left parenthesis, u r l, right parenthesis, semicolon. Line 16, indented 3 times: Scene, scene, equals, new, Scene, left parenthesis, root, comma, 300, comma, 275, right parenthesis, semicolon. Line 17, indented 3 times: stage, dot, set Title, left parenthesis, open quotes, Test, close quotes, right parenthesis, semicolon. Line 18, indented 3 times: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Lien 19, indented 3 times: stage, dot, show, left parenthesis, right parenthesis, semicolon. Line 20, indented twice: right brace. Line 21, indented twice: catch, left parenthesis, Exception, e, right parenthesis. Line 22, indented twice: Left brace. Line 23, indented 3 times: System, dot, out, dot, print l n, left parenthesis, e, dot, get Message, left parenthesis, right parenthesis, right parenthesis, semicolon. Line 24, indented twice: right brace. Line 25, indented once: right brace. Line 26, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 27, indented once: left brace. Line 28, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 29, indented once: right brace. Line 30: right brace.

Back to Code

Error message during compilation of code in question 59. Program code. In the code, the words in the variable names are merged. Line 1: java, dot, lang, dot, Null Pointer Exception, colon, Location is required.

Back to Code

X M L code in question 60. Program code. In the code, the words in the variable names are merged. Line 1: Left angle bracket, question mark, x m l, version, equals, open quotes, 1.0, close quotes, encoding, equals, open quotes, U T F hyphen 8, close quotes, question mark, right angle bracket. Line 2: Left angle bracket, question mark, import, java f x, dot, scene, dot, control, dot, asterisk, question mark, right angle bracket. Line 3: Left angle bracket, question mark, import, java f x, dot, scene, dot, layout, dot, asterisk, question mark, right angle bracket. Line 4: Left angle bracket, V Box, x m l n s, colon, f x, equals, open quotes, h t t p, colon, forward slash, forward slash, java f x, dot, com, forward slash, f x m l, close quotes. Line 5, indented a few times: alignment, equals, open quotes, center, close quotes, spacing, equals, open quotes, 20, close quotes, right angle bracket. Line 6, indented once: Label, text, equals, Welcome, forward slash, right angle bracket. Line 7, indented once: Left angle bracket, Label, text, equals, open quotes, F X M L Test, close quotes, forward slash, right angle bracket. Line 8: Left angle bracket, forward slash, V Box, right angle bracket.

Back to Code

Error message when the code in question 60 is executed. Program code. In the code, the words in the variable names are merged. Line 1: java f x, dot, f x m l, dot, Load Exception, colon. Line 2: f x m l, colon, e x 60, dot, f x m l, colon, 6.

Back to Code

Code in X M L file and program in question 61. Code in the X M L file. Program code. In the code, the words in the variable names are merged. Line 1: Left angle bracket, question mark, x m l, version, equals, open quotes, 1.0, close quotes, encoding, equals, open quotes, U T F hyphen 8, close quotes, question mark, right angle bracket. Line 2: Left angle bracket, question mark, import, java f x, dot, scene, dot, control, dot, asterisk, question mark, right angle bracket. Line 3: Left angle bracket, question mark, import, java f x, dot, scene, dot, layout, dot, asterisk, question mark, right angle bracket. Line 4: Left angle bracket, V Box, f x, colon, controller, equals, open quotes, Controller 61, close quotes. Line 5, indented a few times: x m l n s, colon, f x, equals, open quotes, h t t p, colon, forward slash, forward slash, java f x, dot, com, forward slash, f x m l, close quotes. Line 6, indented a few times: alignment, equals, open quotes, center, close quotes, spacing, equals, open quotes, 10, close quotes, right angle bracket. Line 7, indented once: Left angle bracket, Button, f x, colon, i d, equals, open quotes, button, close quotes, text, equals, open quotes, GO, close quotes. Line 8, indented a few times: on Action, equals, open quotes, hash, go, close quotes, forward slash, right angle bracket. Line 9: Left angle bracket, forward slash, V Box, right angle bracket. Code in the program file. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, event, dot, Action Event, semicolon. Line 2: import, java f x, dot, f x m l, dot, F X M L, semicolon. Line 3: import, java f x, dot, scene, dot, control, dot, asterisk, semicolon. Line 4: public, class, Controller 61. Line 5: Left brace. Line 6, indented once: protected, void, go, left parenthesis, Action Event, event, right parenthesis. Line 7, indented once: Left brace. Line 8, indented twice: System, dot, out, dot, print l n, left parenthesis, open quotes, Inside go, close quotes, right parenthesis, semicolon. Line 9, indented once: right brace. Line 10: right brace.

Back to Code

Error message when the code in question 60 is executed. Program code. In the code, the words in the variable names are merged. Line 1: java f x, dot, f x m l, dot, Load Exception, colon, Error resolving on Action, equals, open single quotes, hash, go, close single quotes, comma. Line 2: either the event handler is not in the Namespace or there is. Line 3: an error in the script.

Back to Code

Program code in question 62. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, application, dot, Application, semicolon. Line 2: import, java f x, dot, scene, dot, Scene, semicolon. Line 3: import, java f x, dot, stage, dot, Stage, semicolon. Line 4: public, class, Test 62, extends, Application. Line 5: Left brace. Line 6, indented once: public, void, start, left parenthesis, Stage, stage, right parenthesis. Line 7, indented once: Left brace. Line 8, indented twice: E x 62, root, equals, new, E x 62, left parenthesis, right parenthesis, semicolon. Line 9, indented twice: Scene, scene, equals, new, Scene, left parenthesis, root, comma, 300, comma, 275, right parenthesis, semicolon. Line 10, indented twice: stage, dot, set Title, left parenthesis, open quotes, Test, close quotes, right parenthesis, semicolon. Line 11, indented twice: stage, dot, set Scene, left parenthesis, scene, right parenthesis, semicolon. Line 12, indented once: right brace. Line 13, indented once: public, static, void, main, left parenthesis, String, left square brace, right square brace, a r g s, right parenthesis. Line 14, indented once: Left brace. Line 15, indented twice: launch, left parenthesis, a r g s, right parenthesis, semicolon. Line 16, indented once: right brace. Line 17: right brace.

Back to Code

Program code in question 63. Program code. In the code, the words in the variable names are merged. Line 1: import, java f x, dot, scene, dot, control, dot, asterisk, semicolon. Line 2: import, java f x, dot, scene, dot, layout, dot, asterisk, semicolon. Line 3: import, java f x, dot, event, dot, asterisk, semicolon. Line 4: public, class, E x 63, extends, V Box. Line 5: Left brace. Line 6, indented once: private, Button, button, semicolon. Line 7, indented once: private, Label, label, semicolon. Line 8, indented once: public, E x 63, left parenthesis, right parenthesis. Line 9, indented once: left brace. Line 10, indented twice: super, left parenthesis, right parenthesis, semicolon. Line

11, indented twice: label, equals, new, Label, left parenthesis, open quotes, HI, close quotes, right parenthesis, semicolon. Line 12, indented twice: button, equals, new, Button, left parenthesis, open quotes, GO, close quotes, right parenthesis, semicolon. Line 13, indented twice: get Children, left parenthesis, right parenthesis, dot, add, left parenthesis, label, right parenthesis, semicolon. Line 14, indented twice: get Children, left parenthesis, right parenthesis, dot, add, left parenthesis, button, right parenthesis, semicolon. Line 15, indented once: right brace. Line 16, indented once: private, class, Button Handler, implements, Event Handler, left angle bracket, Action Event, right angle bracket. Line 17, indented once: left brace. Line 18, indented twice: public, void, handle, left parenthesis, Action Event, a e, right parenthesis. Line 19, indented twice: left brace. Line 20, indented 3 times: label, dot, set Text, left parenthesis, open quotes, Hello, close quotes, right parenthesis, semicolon. Line 21, indented twice: right brace. Line 22, indented once: right brace. Line 23: right brace.

Back to Code

Unix permission command format. c h mod, x y z, file name.

Back to Code

Contents of a file that contains a list of items to be auctioned. Line 1: Olds mobile, comma, olds mobile dot g i f, comma, 100. Line 2: World Cup soccer ticket, comma, soccer Tickets, dot, g i f, comma, 50. Line 3: Trip for 2 to Rome, comma, trip, dot, g i f, comma, 100.

Back to Code

An example illustration indicating the use of color in program code. The color illustrates the syntax of the code as listed in an I D E tool.

Back to Example

An example illustration meant to introduce how figures are used to illustrate and summarize the concept at hand. In this example, a flowchart is listed.

Back to Figure

An example illustration meant to introduce how tables are used to illustrate and summarize the concept at hand. In this example, a flowchart is listed. A table that details access modifiers is listed in this example.

Back to Table

The Look it Up icon that is used to indicate that the student may need to perform some research to answer a question and write the required code.

Back to Figure

A table listing a few simple concepts in Python and Java. Python: Hash is used for single line comments. Program code. In the code, the words in the variable names are merged. Line 1: Hash, This is a comment. Java: Forward slash, forward slash, is used for single line comments. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, forward slash, This is a comment. Python: Triple open single quotes and triple close single quotes are used to delimit multiple line comments. Program code. In the code, the words in the variable names are merged. Line 1: Triple open single quotes, This is a comment that spans over several lines, Triple close single quotes. Java: Forward slash, asterisk, and, asterisk, forward slash, are used to delimit multiple line comments. Program code. In the code, the words in the variable names are merged. Line 1: Forward slash, asterisk, This is a comment that spans over several lines, asterisk, forward slash. Python: There is no need to end a statement with a semicolon. Data types are implicit. We do not need to declare a variable, we just use it. Program code. In the code, the words in the variable names are merged. Line 1: age, equals, 18. Line 2: g p a, equals, 3.7. Java: Every statement ends with a semicolon. Data types are explicit. A variable must be declared before using it. Program code. In the code, the words in the variable names are merged. Line 1: i n t, age, semicolon. Line 2: age, equals, 18, semicolon. Line 3: double, g p a, equals, 3.7, semicolon. Python: Forward slash, is used floating point division, forward slash, forward slash, is used for integer division. Program code. In the code, the words in the variable names are merged. Line 1: average, equals, 373, forward slash, 4. Line 2: hash, floating point division. Line 3: quarters, equals, 102, forward slash, forward slash, 25. Line 4: hash, integer division. Java: The type of division (floating point or integer) is based on the data types of the two operands. Program code. In the code, the words in the variable names are merged. double, average, equals, 373.0, forward slash, 4, semicolon. Line 2: forward slash, forward slash, floating point division. Line 3: i n t, quarters, equals, 102, forward slash, 25, semicolon. Line 4: forward slash, forward slash, integer division. Python: Single quotes and double quotes have the same meaning. Program code. In the code, the words in the variable names are merged. Line 1: grade, equals, open single quotes, A, close single quotes. Line 2: city, equals, open quotes, New York, close quotes. Java: Single quotes are used for characters, double quotes are used for Strings. Program code. In the code, the words in the variable names are merged. Line 1: char, grade, equals, open single quotes, A, close single quotes, semicolon. Line 2: String, city, equals, open quotes, New York, close quotes, semicolon. Python: There is no formal concept of a constant, but using uppercase for a variable is good practice to denote that we should not change its value. Program code. In the code, the words in the variable names are merged. Line 1: DAYS, equals, 365. Line 2: Hash, Please do not change the. Line 3: Hash, value of DAYS. Java: The final keyword is used to declare constants. The value of a constant cannot be changed. Program code. In the code, the words in the variable names are merged. Line 1: final, i n t, DAYS, equals, 365, semicolon. Line 2: Forward slash, forward slash, DAYS' value cannot be. Line 3: Forward slash, forward slash, changed. Python: Indentation counts. Parentheses around the condition are not needed, and a colon precedes the indented statements. Program code. In the code, the words in the variable names are merged. Line 1: if, age, right angle bracket, equals, 18, colon. Line 2, indented once: print, left parenthesis, open quotes, You can vote, close quotes, right parenthesis. Line 3, indented once: print, left parenthesis, close quotes, Congratulations, close quotes, right parenthesis. Java: Indentation does not count, but we use it for style and readability. Parentheses are required around conditions. If there is more than one statement attached to a selection or looping construct, we use curly braces for the block. Program code. In the code, the words in the variable names are merged. Line 1: if, left parenthesis, age, right angle bracket, equals, 18, right parenthesis. Line 2: Left brace. Line 3, indented once: System, dot, out, dot, print l n, left parenthesis, open quotes, You can vote, close quotes, right parenthesis, semicolon. Line 3, indented once: System, dot, out, dot, print l n, left parenthesis, open quotes, Congratulations, close quotes, right parenthesis, semicolon. Line 4: right brace. Python: The logical operators are and, or, and not. Program code. In the code, the words in the variable names are merged.

Line 1: if, age, greater than or equals, 18, and, age, less than or equals, 65, colon. Line 2, indented once: print, left parenthesis, open quotes, Hi, close quotes, right parenthesis. Java: The logical operators are ampersand, ampersand (for and), pipe, pipe, (for or), and exclamation mark (for not). Program code. In the code, the words in the variable names are merged. Line 1: if, left parenthesis, age, greater than or equals, 18, and, age, less than or equals, 65, right parenthesis. Line 2, indented once: System, dot, out, dot, print l n, left parenthesis, open quotes, Hi, close quotes, right parenthesis, semicolon. Python: The keyword def is used for functions. The parameter list is a comma delimited list of variable names. The function header is followed by a colon. The body of the function is indented. Program code. In the code, the words in the variable names are merged. Line 1: def, sum, left parenthesis, a, comma, b, right parenthesis, colon. Line 2, indented once: return, a, plus, b. Java: The parameter list of a function (called method in Java) is a comma delimited list of variable names and their respective data types. The method header includes the return data type (void if the method does not return anything). The body of the method is inside a set of curly braces. Indentation is optional but recommended for better readability. Program code. In the code, the words in the variable names are merged. Line 1: i n t, sum, left parenthesis, i n t, a, comma, i n t, b, right parenthesis. Line 2: Left brace. Line 3, indented once: return, a, plus, b, semicolon. Line 4: right brace.
